Foreword

Many applications require bearings that are suitable for oscillating movements and that can accommodate misalignment. Rolling bearings only partly fulfil these requirements as they are generally designed for continuous rotation and can only accommodate limited misalignment.

Therefore, SKF manufactures spherical plain bearings and rod ends to provide an economical solution to these challenges.

This catalogue presents the current assortment of SKF spherical plain bearings and rod ends.

Structure of the catalogue

The catalogue starts with general product information, followed by nine main chapters, which are marked with numbered blue tabs in the right margin:

- Chapter 1 provides design and application recommendations.
- Chapters 2 to 7 describe the various bearing and rod end types. Each chapter contains descriptions of the products as well as product tables, listing data for selecting a bearing or rod end and designing the bearing arrangement.
- Chapter 8 is an overview about other SKF products and services.
- In chapter 9, all products presented in this catalogue are listed in alphabetical order by designation.

About the data in this catalogue

The data in this catalogue relate to SKF's state-of-the-art technology and production capabilities as of beginning 2010. The data may differ from that shown in earlier catalogues because of revised methods of calculation, redesign or technological developments. For example, the following new information and product data

have been included for radial spherical plain bearings:

- Bearings in the TX series have been added and are available with bore diameters up to 800 mm.
- Bearings in the maintenance-free series are fitted with LS seals as standard.
- Bearings with the sliding material FSA have been replaced by the FBAS design.
- Bearings requiring maintenance are also available with LS seals.
- Part of the inch assortment is also available with LS seals.

SKF reserves the right to make continuing improvements to SKF products with respect to materials, design and manufacturing methods, as well as changes necessitated by technological developments.

The units used in this catalogue are in accordance with ISO (International Organization for Standardization) standard 1000:1992, and SI (Système International d'Unités). Unit conversions are listed in the table on [page 7](#).

Other SKF catalogues

The total SKF product portfolio is much broader than just spherical plain bearings and rod ends. Product information is also available via the SKF website at www.skf.com. The *SKF Interactive Engineering Catalogue* provides not only product information, but also online calculation tools, CAD drawings in various formats, and search and selection functions.

The main printed SKF catalogues are:

- General catalogue
- Needle roller bearings
- High-precision bearings
- Y-bearings and Y-bearing units

- Bearing housings
- Slewing bearings
- Linear motion standard range
- SKF Maintenance and Lubrication Products
- Centralized lubrication systems
- Industrial shaft seals
- SKF Power transmission products

For additional information about SKF products and services, contact your local SKF representative or SKF Authorized Distributor.

More advantages

SKF aims to deliver industry-leading, high value products, services and knowledge-engineered solutions. Many of the product's capabilities contribute to the overall value customers receive in making SKF their supplier of choice, such as:

- simplified bearing selection
- short delivery times
- worldwide availability
- commitment to product innovation
- state-of-the-art application solutions
- extensive engineering and technology knowledge in virtually every industry

This is SKF

From one simple but inspired solution to a misalignment problem in a textile mill in Sweden, and fifteen employees in 1907, SKF has grown to become a global industrial knowledge leader. Over the years we have built on our expertise in bearings, extending it to seals, mechatronics, services and lubrication systems. Our knowledge network includes 46 000 employees, 15 000 distributor partners, offices in more than 130 countries, and a growing number of SKF Solution Factory sites around the world.

Research and development

We have hands-on experience in over 40 industries, based on our employees' knowledge of real life conditions. In addition our world-leading experts and university partners who pioneer advanced theoretical research and development in areas including tribology, condition monitoring, asset management and bearing life theory. Our ongoing commitment to

SKF Solution Factory makes SKF knowledge and manufacturing expertise available locally, to provide unique solutions and services to our customers.

research and development helps us keep our customers at the forefront of their industries.

Meeting the toughest challenges

Our network of knowledge and experience along with our understanding of how our core technologies can be combined helps us create innovative solutions that meet the toughest of challenges. We work closely with our customers throughout the asset life cycle, helping them to profitably and responsibly grow their businesses.

Working for a sustainable future

Since 2005, SKF has worked to reduce the negative environmental impact from our own operations and those of our suppliers. Our continuing technology development introduced the SKF BeyondZero portfolio of products and services which improve efficiency and reduce energy losses, as well as enable new technologies harnessing wind, solar and ocean power. This combined approach helps reduce the environmental impact both in our own operations and in our customers'.

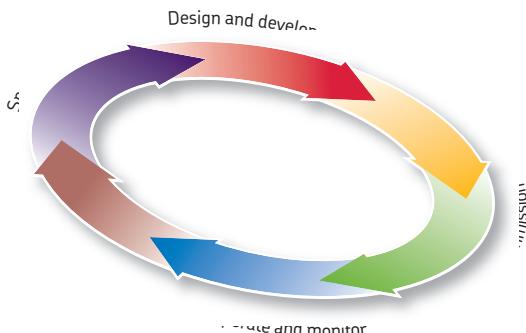

Working with SKF IT and logistics systems and application experts, SKF Authorized Distributors deliver a valuable mix of product and application knowledge to customers worldwide.

SKF – the knowledge engineering company

Our knowledge – your success

SKF Life Cycle Management is how we combine our technology platforms and advanced services, and apply them at each stage of the asset life cycle, to help our customers to be more successful, sustainable and profitable.

Working closely with you

Our objective is to help our customers improve productivity, minimize maintenance, achieve higher energy and resource efficiency, and optimize designs for long service life and reliability.

Innovative solutions

Whether the application is linear or rotary or a combination of the two, SKF engineers can work with you at each stage of the asset life cycle to

improve machine performance by looking at the entire application. This approach doesn't just focus on individual components like bearings or seals. It looks at the whole application to see how each component interacts with the next.

Design optimization and verification

SKF can work with you to optimize current or new designs with proprietary 3-D modelling software that can also be used as a virtual test rig to confirm the integrity of the design.

Bearings

SKF is the world leader in the design, development and manufacture of high performance rolling bearings, plain bearings, bearing units and housings.

Machinery maintenance

Condition monitoring technologies and maintenance services from SKF can help minimize unplanned downtime, improve operational efficiency and reduce maintenance costs.

Sealing solutions

SKF offers standard seals and custom engineered sealing solutions to increase uptime, improve machine reliability, reduce friction and power losses, and extend lubricant life.

Mechtronics

SKF fly-by-wire systems for aircraft and drive-by-wire systems for off-road, agricultural and forklift applications replace heavy, grease or oil consuming mechanical and hydraulic systems.

Lubrication solutions

From specialized lubricants to state-of-the-art lubrication systems and lubrication management services, lubrication solutions from SKF can help to reduce lubrication related downtime and lubricant consumption.

Actuation and motion control

With a wide assortment of products – from actuators and ball screws to profile rail guides – SKF can work with you to solve your most pressing linear system challenges.

Properties

Spherical plain bearings

Spherical plain bearings are standardized, ready-to-mount, mechanical components that enable multi-directional, self-aligning movements. The inner ring has a spherical convex outside diameter, while the outer ring has a correspondingly concave inside diameter (**→ fig. 1**). The forces acting on the bearing may be static or may occur when the bearing makes oscillating or recurrent tilting and slewing movements at relatively low speeds.

Design advantages inherent to spherical plain bearings include the ability to:

- accommodate misalignment (**→ fig. 2**)
- virtually eliminate edge stresses and excessive stressing of adjacent components (**→ fig. 3**)
- accommodate deformation of surrounding components in operation (**→ fig. 4**)
- accommodate wide manufacturing tolerances and the use of cost-effective, welded assemblies (**→ fig. 5**)

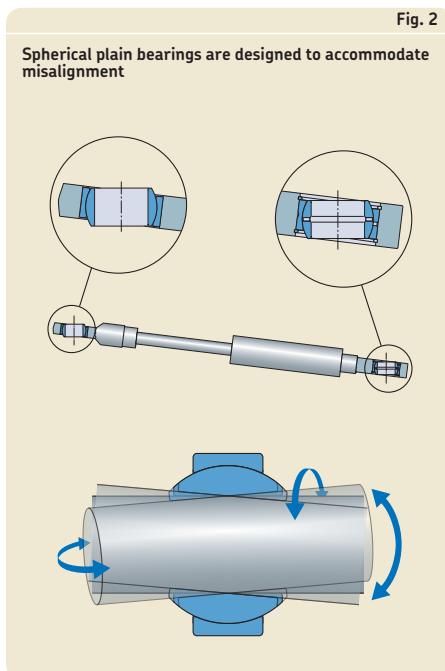

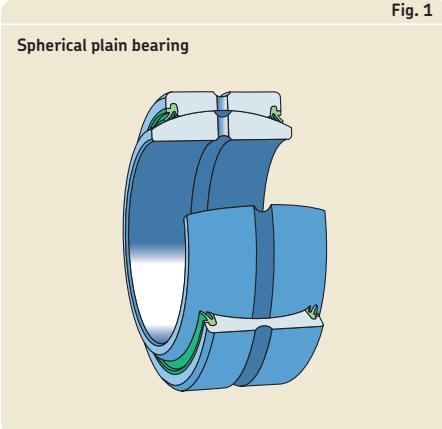

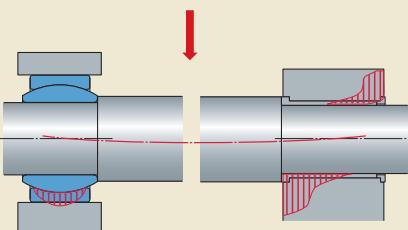

Fig. 3

Compared to bushings, spherical plain bearings provide higher reliability, as the chance of edge stresses and overloading are virtually non-existent

Rod ends

Spherical plain bearing rod ends are bearing units that consist of a spherical plain bearing in the eye-shaped head of the rod end housing (→ fig. 6). They are used primarily on the ends of hydraulic or pneumatic pistons to join the cylinder to an associated component via an internal (female) thread, external (male) thread or a welding shank (→ fig. 7 on page 16).

SKF supplies rod ends with a threaded shank with a right-hand thread as standard. With the exception of rod ends with the designation suffix VZ019, all rod ends are also available with a left-hand thread. They are identified by the designation prefix L.

Fig. 4

Shaft deflection does not have a negative influence on bearing service life, the shaft or housing

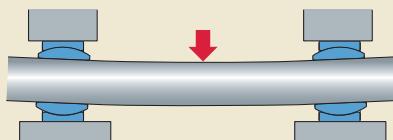

Fig. 5

Spherical plain bearings can accommodate the wide manufacturing tolerances found in cost-effective welded assemblies

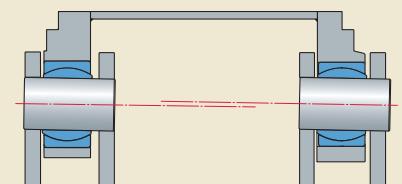

Fig. 6

Rod end with a male thread

Bearing designs and features

SKF spherical plain bearings and rod ends are an excellent choice for applications that require total design economy. These state-of-the-art products are available in a wide assortment of designs, dimension series and sizes to meet the needs of a particular application. **Fig. 7** shows the general bearing and rod end types.

Whether the application calls for a large spherical plain bearing or a small rod end assembly, both are available from SKF and offer:

- long service life
- minimal maintenance
- high operational reliability

SKF spherical plain bearings and rod ends, produced with standard dimensions, are available

worldwide, making them readily accessible whenever and wherever they are needed.

Economic considerations and unparalleled design characteristics are not the only reasons that SKF spherical plain bearings and rod ends are the ultimate solution for any plain bearing application. Their designs, materials and manufacturing quality enable long service life and high reliability even in the most demanding applications.

Bearings and rod ends requiring maintenance

Bearings and rod ends requiring maintenance must be greased prior to being put into operation. With the exception of a few applications, they must be relubricated periodically.

SKF steel/steel radial spherical plain bearings are made of bearing steel and are through-hardened. The high-strength sliding contact surfaces are phosphated and treated with a special running-in lubricant. These bearings are used primarily in applications where there are:

- heavy static loads
- heavy alternating loads
- shock loads

They are also relatively insensitive to contaminants and high temperatures.

To facilitate relubrication, lubrication holes and grooves are provided in both the inner and outer rings of all steel/steel radial spherical plain bearings – with the exception of a few small sizes. SKF steel/bronze rod ends also require relubrication. However, requirements are less stringent than for steel/steel rod ends, as the emergency running properties of bronze are more forgiving than steel.

The multi-groove system

Standard steel/steel radial spherical plain bearings that must accommodate minor alignment movements under very heavy, constant direction loads are prone to lubricant starvation. To maximize the effects of the lubricant under these conditions, SKF has developed the multi-groove system and manufactures all metric steel/steel radial spherical plain bearings with an outside diameter $D \geq 150$ mm with the multi-groove system on the sliding surface of the outer ring as standard (→ **fig. 8**). Metric steel/steel radial spherical plain bearings with an outside diameter $D < 150$ mm can be supplied with the multi-groove system on request. These bearings are identified by the designation suffix ESL.

These lubrication grooves provide the following benefits:

- improved lubricant supply to the loaded zone
- enlarged lubricant reservoir in the bearing
- enable relubrication under load
- extended relubrication intervals
- space for wear particles and contaminants
- extended grease life

The main benefit of the multi-groove system is that it improves lubricant distribution in the heavily loaded zone to extend service life and/or maintenance intervals.

Fig. 8

Steel/steel radial spherical plain bearing with the multi-groove system

Maintenance-free, long-life sliding contact surfaces

"Maintenance-free" is an industry-wide term used to describe plain bearings and rod ends with self-lubricating sliding contact surface combinations. The term maintenance-free does not imply that these bearings should not be inspected as part of a regularly scheduled maintenance program.

These so-called maintenance-free bearings and rod ends offer a number of advantages for OEMs and end users alike. These advantages, which include minimal maintenance and reduced lubricant consumption, quickly compensate for the difference in the initial purchase price when compared to standard steel/steel bearing solutions. And of course, the impact that maintenance-free bearings have on the environment is an added benefit.

To offer maintenance-free solutions for the greatest number of applications, SKF produces spherical plain bearings and rod ends with different sliding contact surface combinations (→ fig 9). These combinations, which in some cases are size dependent, include:

- steel/PTFE (polytetrafluoroethylene) sintered bronze
- steel/PTFE fabric
- steel/PTFE FRP (fibre reinforced polymer)

Maintenance-free bearings can operate without grease, and therefore do not need to be relubricated. Depending on the sliding surfaces, grease

can improve bearing service life or can have a negative effect on it. Therefore, SKF does not recommend the use of lubricants for bearings with steel/PTFE sintered bronze or steel/PTFE fabric sliding contact surface combinations, whereas initial lubrication followed by occasional relubrication of steel/PTFE FRP bearings can extend the service life of the bearing.

Be aware that "maintenance-free" refers to bearing service life only, and does not refer to the service life of an application or general maintenance intervals of other machine parts in the application. For detailed information about the life of spherical plain bearings or rod ends, refer to the section *Basic rating life* starting on **page 39**. The basic rating life as a guideline value for the service life under certain operating conditions can be calculated using the information provided in the section *Basic rating life calculation* starting on **page 51**.

Self-lubricating, dry sliding materials are not as stiff as steel and consequently are subject to greater deformation under load than steel. These sliding materials are also more sensitive than steel to alternating or shock loads. If either of these load conditions exists, contact the SKF application engineering service.

Maintenance-free bearings and rod ends are designed for applications where:

- load direction is constant and may be heavy
- low coefficient of friction is necessary
- relubrication is not possible or difficult

Fig. 9

Maintenance-free, long life sliding contact surfaces

Optional SKF design features

A choice of materials

For most applications, SKF spherical plain bearings made of standard bearing steel requiring maintenance are an excellent choice. However, for difficult operating environments, SKF maintenance-free stainless steel spherical plain bearings may be preferred. For other material options, e.g. surface treatments, contact the SKF application engineering service.

With or without seals

Most popular sizes of SKF spherical plain bearings are available either open (without seals) or sealed on both sides (→ fig. 10). Standard sealed bearings can increase the service life of a bearing and save space, while reducing inventory and assembly costs. Maintenance-free bearings without seals have to be protected against contaminants.

Spherical plain bearings fitted on both sides with the SKF RS double lip seal are very effective, under normal operating conditions, at keeping contaminants away from the sliding contact surfaces. These seals also effectively retain the grease and therefore are appropriate for bearings requiring maintenance.

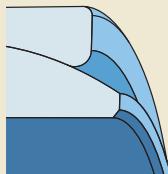

Maintenance-free bearings and all bearings operating in highly contaminated environments should be fitted with the SKF LS triple-lip heavy-duty contact seal (→ page 79). They are reinforced with a steel insert and have three seal lips. These very effective seals protect the bearing against contaminants and enhance the operational reliability of the spherical plain bearing.

Wide operating temperature range

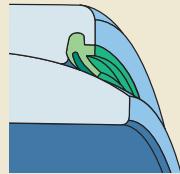

SKF spherical plain bearings and rod ends can operate effectively over a wide temperature range. The operating temperature range of open (without seals) steel/steel radial spherical plain bearings is -50 to +200 °C.

Fig. 10

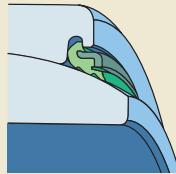

Many sealing problems can be solved economically and in a space-saving manner using sealed bearings

without seal
(open design)

double-lip seal
(RS design)

triple-lip heavy-duty seal
(LS design)

Multi-purpose performance

Typical applications

Long service life, high reliability and minimal maintenance are some of the features of SKF spherical plain bearings and rod ends. SKF's wide assortment of spherical plain bearings and rod ends is versatile enough to be used in a variety of applications that encompass almost all sectors of industry, including:

- agriculture
- construction
- forklift trucks
- material handling
- metals
- mining
- railways
- trucks
- wind energy

Application examples

Suspended roof

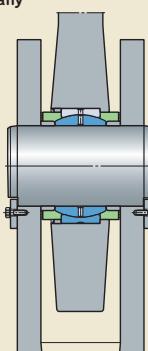

SKF steel/steel radial spherical plain bearings are in service in an unusual and world-renowned application, the roof of the Olympic Stadium in Munich, Germany ([→ fig. 11](#)). The roof is constructed of a number of pre-stressed steel cables in a network. The nodal points of the network must be torque-free. That is where 225 standard SKF steel/steel radial spherical plain bearings with bore diameters ranging from 160 to 300 mm are located. The nodes are statically loaded but must enable occasional swinging movements of the roof construction.

Although SKF steel/steel radial spherical plain bearings are typically not maintenance-free, these particular bearings have not been relubricated since the construction of the building in 1972.

What better proof could there be for lasting quality and reliability?

Fig. 11

Nodal points of suspended roof construction of the Olympic Stadium in Munich, Germany

Road roller articulation joint

SKF spherical plain bearings in the articulation joint between the front and rear rollers (\rightarrow fig. 12) enable a road roller to manoeuvre. This joint must be able to withstand very heavy radial loads and high vibration levels. Due to their location, the bearings should be protected as they are exposed to a variety of contaminants including dust, dirt, water and hot tarmac, which promote premature wear and corrosion.

SKF maintenance-free spherical plain bearings help to eliminate the need for relubrication, and reduce the total cost of ownership.

Truck twin-axle supports

An SKF spherical plain bearing arrangement on the truck twin-axle support provides even load

distribution between the two axles for trucks driving on rough roads or off-highway conditions (\rightarrow fig. 13). This bearing arrangement is subjected to heavy loads and, depending on the conditions, heavy shock loads, and frequent alignment movements.

These bearings are located behind the tires in an area that is very difficult to access, making it imperative that sudden bearing damage or failure, requiring immediate roadside repairs, be avoided at all cost. A pair of SKF angular contact spherical plain bearings mounted in a back-to-back arrangement can help prevent these emergencies. These bearings, which can withstand all the rigours of truck duty, are simple to install and easy to maintain.

Fig. 12

Road roller articulation joint

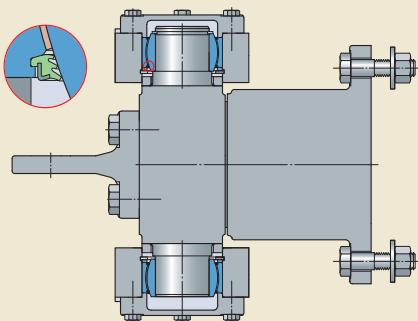

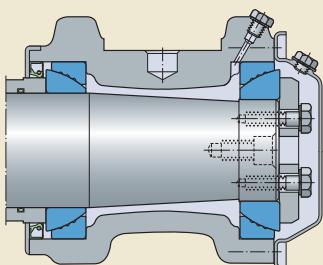

Fig. 13

Truck twin-axle supports

Dam gates

Segment gates for dams and other barrages are home to large-size SKF maintenance-free spherical plain bearings (→ **fig. 14**). The reference list is very long – with over 3 000 applications to date.

As main bearings, they compensate for shaft misalignment, caused by thermal expansion and contraction, elastic deformation of the dam gates as well as changes caused by settling of the foundation. These bearings cope with the heavy radial loads caused by water pressure as well as axial loads that arise from the inclined position of the support arms.

In addition, SKF spherical plain bearings not only serve as heavily loaded bearings under static conditions, they also operate in the frequently used linkage attachments of the lifting and plunger cylinders as well as the flaps.

Hydraulic and pneumatic cylinders

SKF steel/steel and steel/bronze rod ends are frequently used on hydraulic and pneumatic cylinders (→ **fig. 15**). Acting as the link between the cylinder and its attachments, they are able to transmit heavy mechanical loads.

Hydraulic cylinders (e.g. to ISO 8132) are often fitted with steel/steel rod ends with a female thread that can be secured (compressible) on one end and a steel/steel rod end with a welding shank on the other.

These types of hydraulic cylinders can be found in all types of construction equipment, agricultural machinery, lifting equipment and shutters, recycling depot presses as well as other heavily loaded manoeuvring equipment.

In pneumatic cylinders where working pressures regularly reach 1 MPa, steel/bronze rod ends and maintenance-free rod ends are typically used at the end of the piston rod. At the opposite end, SKF rod ends with a welding shank are used.

Newspaper conveyor

Speed and flexibility are all-important when producing newspapers, not only in the printing process, but also in distribution. The conveyor system from the printing press to the loading dock is a very important component if the newspapers are to be delivered on time.

The endless conveyor chain is one such system. It consists of a multitude of links, which together provide the speed and flexibility required. **Fig. 16** shows an application where more than 1 000 SKF maintenance-free spherical plain bearings with the sliding contact surface combination steel/PTFE sintered bronze are used. The bearings have been in daily service without maintenance for many years.

- 2b Rod end shank, with an external (male) thread. Shanks are also available with an internal (female) thread or with a welding shank.
- 3 Grease fitting

Fig. 2

Bearing types

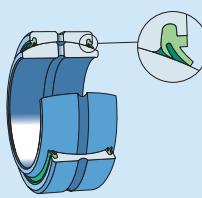

All the products listed below belong to the SKF standard assortment:

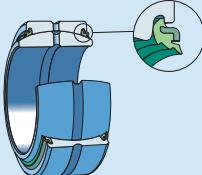

- radial spherical plain bearings requiring maintenance
- maintenance-free radial spherical plain bearings
- angular contact spherical plain bearings
- thrust spherical plain bearings
- steel/steel and steel/bronze rod ends requiring maintenance
- maintenance-free rod ends

If the standard assortment does not meet the requirements of an application, SKF can produce special bearings or rod ends, provided quantities are sufficient to enable manufacturing economy.

Maintenance-free radial spherical plain bearings

See chapter 3 starting on **page 125**

Bearing design	Designation/ bore diameter range	Characteristics
Sliding contact surface combination: Steel/PTFE sintered bronze Suitable for heavy, constant direction loads, where low friction is required; limited suitability for alternating loads, shock loads.		
	GE .. C $d = 4 - 30 \text{ mm}$ GE .. CJ2 $d = 35 - 60 \text{ mm}$	Open (without seals), self-lubricating sliding surfaces have to be externally protected from contaminants
	GEH .. C $d = 10 - 25 \text{ mm}$	Open (without seals), self-lubricating sliding surfaces have to be externally protected from contaminants; wider inner ring and larger outside diameter compared to GE .. C series, to enable higher load ratings and larger tilt angle

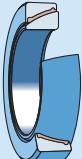

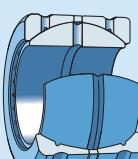

Bearing design Maintenance-free radial spherical plain bearings	Designation/ bore diameter range	Characteristics
Sliding contact surface combination: Steel/PTFE fabric Suitable for very heavy, constant direction loads, where low friction is required; limited suitability for alternating loads, shock loads		
	GE .. TXE-2LS $d = 20 - 90 \text{ mm}$ GEZ .. TXE-2LS $d = 1 - 3.75 \text{ in}$ GE .. TXG3E-2LS $d = 20 - 60 \text{ mm}$	High performance bearing with a triple-lip heavy-duty seal on both sides, outer ring fractured at one point, self-lubricating sliding surfaces GE .. TXG3E-2LS series in stainless steel execution for use in corrosive environments
	GE .. TXA-2LS $d = 100 - 300 \text{ mm}$ GEZ .. TXA-2LS $d = 4 - 6 \text{ in}$ GE .. TXG3A-2LS $d = 70 - 200 \text{ mm}$	High performance bearing with a triple-lip heavy-duty seal on both sides, axially split outer ring that is held together by one band, self-lubricating sliding surfaces GE .. TXG3A-2LS series with rings made of stainless steel for use in corrosive environments
	GE .. TXGR $d = 12 - 17 \text{ mm}$	Open (without seals), stainless steel execution for use in corrosive environments, self-lubricating sliding surfaces have to be externally protected from contaminants
	GEC .. TXA-2RS $d = 320 - 400 \text{ mm}$	High performance bearing with a double-lip seal on both sides, self-lubricating sliding surfaces, axially split outer ring that is held together by two bands
	GEC .. TXA-2RS $d = 420 - 800 \text{ mm}$	High performance bearing with a double-lip seal on both sides, self-lubricating sliding surfaces, axially split outer ring that is bolted together

Selection of bearing types

Bearing design	Designation/ bore diameter range	Characteristics
Maintenance-free radial spherical plain bearings		
Sliding contact surface combination: Steel/PTFE fabric Suitable for very heavy, constant direction loads, where low friction is required; limited suitability for alternating loads, shock loads		
	GEH ..TXE-2LS $d = 20 - 80 \text{ mm}$	High performance bearing with a triple-lip heavy-duty seal on both sides; self-lubricating sliding surfaces, wider inner ring and larger outside diameter compared to GE .. TXE-2LS series, to enable higher load ratings and larger tilt angle
	GEH ..TXG3E-2LS $d = 20 - 50 \text{ mm}$	GEH .. TXG3E-2LS series with rings made of stainless steel for use in corrosive environments
	GEH ..TXA-2LS $d = 90 - 120 \text{ mm}$	High performance bearing with a triple-lip heavy-duty seal on both sides, self-lubricating sliding surfaces, wider inner ring and larger outside diameter compared to GE .. TXE-2LS series, to enable higher load ratings and larger tilt angle; axially split outer ring that is held together by one band
	GEH ..TXG3A-2LS $d = 60 - 120 \text{ mm}$	GEH .. TXG3A-2LS series with rings made of stainless steel for use in corrosive environments
Sliding contact surface combination: Steel/PTFE FRP Suitable for heavy, constant direction loads, where low friction is required; limited suitability for alternating loads, shock loads; relatively insensitive to contaminants		
	GEC .. FBAS $d = 320 - 1\,000 \text{ mm}$	Open (without seals); axially split outer ring that is bolted together; self-lubricating capability; factory greased; lubrication holes and an annular groove in both rings; does not require relubrication, however, relubrication can extend bearing service life
	GEP .. FS $d = 100 - 1\,000 \text{ mm}$	Open (without seals); radially split outer ring that is separable to facilitate mounting; self-lubricating capability; factory greased; lubrication holes and an annular groove in both rings; does not require relubrication, however, relubrication can extend bearing service life Compared to GEC .. FBAS series, these bearings are wider and have a larger outside diameter for a given shaft size, resulting in a higher basic load rating. However, they have a smaller tilt angle.

Angular contact spherical plain bearings

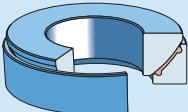

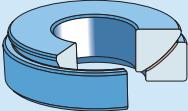

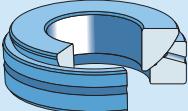

See chapter 4 starting on page 151

Bearing design	Designation/ bore diameter range	Characteristics
Angular contact spherical plain bearings		
Sliding contact surface combination: Steel/PTFE FRP Suitable for single direction axial loads or combined axial and radial loads, low coefficient of friction, relatively insensitive to contaminants	GAC .. F $d = 25 - 120 \text{ mm}$	Open (without seals); self-lubricating capability; factory greased; does not require relubrication, however, relubrication can extend bearing service life
		
Sliding contact surface combination: Steel/PTFE fabric Suitable for single direction axial loads or combined axial and radial loads, very high load carrying capacity and low coefficient of friction	GACD .. TX upon request	Open (without seals), high performance bearing with self-lubricating sliding surface
		
Sliding contact surface combination: Steel/steel Suitable for heavy single direction axial loads or heavy combined axial and radial loads, heavy alternating loads	GACD .. SA upon request GAZ .. SA upon request	Open (without seals), multi-groove system, can be relubricated via lubrication holes and an annular groove in the outer ring
		
Sliding contact surface combination: Steel/steel Double direction angular contact bearing with a standard inner ring, bearing can be used instead of two angular contact bearings in a face-to-face arrangement, suitable for heavy combined radial and axial loads, heavy alternating loads	GEZP(R) .. S upon request	Open (without seals), multi-groove system, can be relubricated via lubrication holes and an annular groove in the inner ring and the two outer rings
		

Selection of bearing types

Thrust spherical plain bearings

See chapter 5 starting on page 159

Bearing design	Designation/ bore diameter range	Characteristics
Thrust spherical plain bearings		
Sliding contact surface combination: Steel/PTFE FRP Suitable for single direction axial loads or combined axial and radial loads, low coefficient of friction, relatively insensitive to contaminants	 GX .. F $d = 17 - 120 \text{ mm}$	Open (without seals); self-lubricating capability; factory greased; does not require relubrication, however, relubrication can extend bearing service life
Sliding contact surface combination: Steel/PTFE fabric Suitable for heavy single direction axial loads or combined axial and radial loads, very high load carrying capacity and low coefficient of friction	 GXD .. TX upon request	Open (without seals), high performance bearing with self-lubricating sliding surface
Sliding contact surface combination: Steel/steel Suitable for heavy single direction axial loads or combined axial and radial loads, heavy alternating loads	 GXD .. SA upon request	Open (without seals), multi-groove system, can be relubricated via lubrication holes and an annular groove in the housing washer

Rod ends with a threaded shank, requiring maintenance

See chapter 6 starting on page 167

Bearing design	Designation/ bore diameter range	Characteristics

Selection of bearing size

Load ratings

There is no standardized method for determining the load ratings of spherical plain bearings and rod ends, nor is there any standardized definition. As different manufacturers define load ratings differently, it is not possible to compare the load ratings of bearings produced by one manufacturer with those of another.

Basic dynamic load rating

The basic dynamic load rating C is used, together with other influencing factors, to determine the basic rating life of spherical plain bearings and rod ends. As a rule, it represents the maximum load that a spherical plain bearing or rod end can accommodate at room temperature when there is movement between the sliding contact surfaces (→ fig. 1). The maximum load in any application should always be considered in relation to the required rating life. The basic dynamic load ratings quoted in the product tables are based on the specific load factor K (→ table 4 on page 45) and the effective projected sliding surface.

Basic static load rating

The basic static load rating C_0 represents the maximum permissible load that a spherical plain bearing or rod end can accommodate when there is no relative movement between the sliding contact surfaces (→ fig. 2).

For spherical plain bearings, the basic static load rating represents the maximum load that the bearing can accommodate at room temperature without inadmissible deforming, fracturing or damaging the sliding contact surfaces.

The basic static load ratings quoted for SKF spherical plain bearings are based on a specific

Fig. 1

Dynamic bearing load

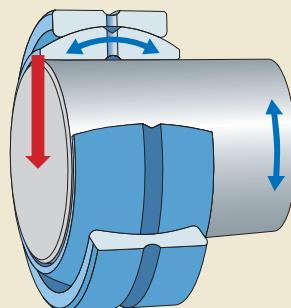

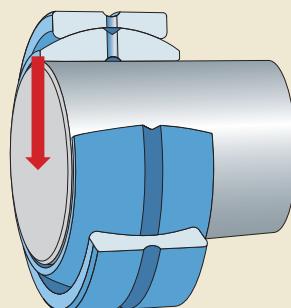

Fig. 2

Static bearing load

static load factor K_0 (→ **table 4** on **page 45**) and the effective projected sliding surface. It is assumed that the bearing is adequately supported. To fully exploit the static load rating of a spherical plain bearing, it is generally necessary to use shafts and housings made of high-strength materials. The basic static load rating must also be considered when bearings are dynamically loaded and subjected to additional heavy shock loads. The total load in these cases must not exceed the basic static load rating.

For rod ends, it is the strength of the housing at room temperature, under a constant load acting in the direction of the shank axis, that is the determining factor. The basic static load rating represents a safety factor of at least 1,2 relative to the yield strength of the material of the rod end housing, under the above conditions.

Basic rating life

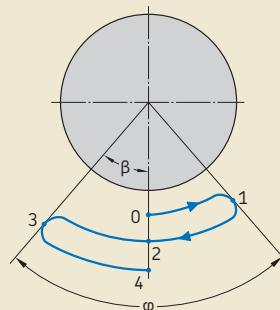

For spherical plain bearings, a lubricant film that fully separates the sliding contact surfaces cannot be formed. Therefore, the sliding contact surfaces make direct contact with each other, resulting in a certain and unavoidable degree of wear. This increases the internal clearance in the bearing.

Regarding the life of spherical plain bearings or rod ends, a distinction is made between the basic rating life and the service life. The basic rating life is a theoretical guideline value, used to estimate the service life. Service life depends on the actual operating conditions and is the actual life achieved by the bearing in service.

The basic rating life is based on a large number of laboratory tests. The bearings were tested for an operating period until a specific increase in bearing clearance or friction occurred (→ **table 1** on **page 40**). The basic rating life considers several influencing factors and can be expressed in operating hours or the number of oscillating movements (→ **fig. 3**). In some cases, however, it is not possible to quantify factors such as contamination, corrosion, and complex kinematic loads. Therefore, the basic rating life can be attained or exceeded by

Fig. 3

Angle of oscillation

$\varphi = \text{angle of oscillation} = 2\beta$
A complete oscillation is from point 0 to point 4 and = 4β

the majority of many apparently identical spherical plain bearings under the same operating conditions. For the calculation methods of the different sliding contact surface combinations as well as calculation examples, refer to the section *Basic rating life calculation* starting on **page 51**.

The service life cannot be calculated as it is too complex to determine and evaluate all the influencing factors. Therefore, depending on the application conditions, the service life may differ from the basic rating life.

NOTE: By using the *SKF Interactive Engineering Catalogue* and its incorporated calculation programs, it is possible to perform the necessary calculations to select a spherical plain bearing with the click of a mouse. The product data necessary for the calculations is automatically put in by selecting a spherical plain bearing or rod end from the product tables. It is then only necessary to fill in the fields for the operating data.

The *SKF Interactive Engineering Catalogue* is available online at www.skf.com.

Selection of bearing size

Table 1

Failure criteria for basic rating life tests		
Sliding contact surface combination	Increase in bearing clearance	Coefficient of friction μ
-	mm	-
Steel/steel	> 0,004 $d_k^{1)}$	0,20
Steel/bronze	> 0,004 $d_k^{1)}$	0,25
Steel/PTFE ²⁾ sintered bronze		
constant direction load	0,2	0,25
alternating direction load	0,4	0,25
Steel/PTFE fabric		
constant direction load	0,3	0,15
alternating direction load	0,6	0,15
Steel/PTFE FRP ³⁾	design and size dependent	0,20

¹⁾ d_k = sphere diameter of the inner ring.

²⁾ Polytetrafluoroethylene.

Fig. 4

Radial load

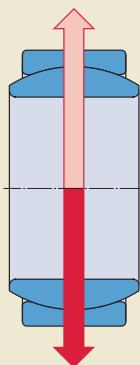

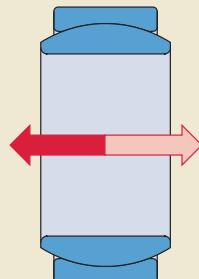

Fig. 5

Axial load

Load

Combined load

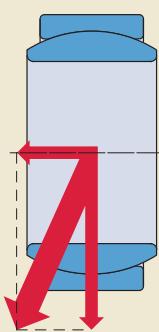

Fig. 6

Constant direction load

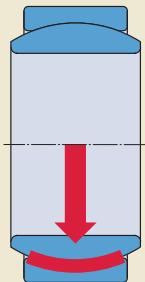

Fig. 7

Alternating direction load

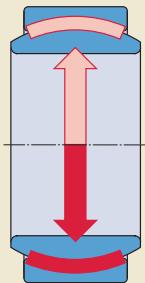

Fig. 8

When considering load, a distinction is made between:

- load direction
 - radial load (\rightarrow fig. 4)
 - axial load (\rightarrow fig. 5)
 - combined (axial and radial) load (\rightarrow fig. 6)
- type of load
 - dynamic load, i.e. there is relative sliding movement in the loaded bearing
 - static load, i.e. there is no relative movement in the loaded bearing
- load conditions
 - constant load (\rightarrow fig. 7), i.e. the direction in which the load is applied does not change and the same part of the bearing (loaded zone) is always subjected to the load
 - alternating load (\rightarrow fig. 8), i.e. change of load direction so that zones at opposite positions in the bearing are alternately loaded and unloaded

Equivalent dynamic bearing load

The load can be inserted directly into the equation for the specific bearing load p (\rightarrow page 46) if the magnitude of the load is constant and if the load acting on:

- radial and angular contact spherical plain bearings is purely radial
- thrust spherical plain bearings is purely axial
- rod ends is purely radial and in the direction of the shank axis

In all other cases it is necessary to calculate the equivalent dynamic bearing load P . If the magnitude of the load is not constant, use the equation provided in the section *Variable load and sliding velocity* (\rightarrow page 61).

Selection of bearing size

Radial spherical plain bearings

Radial spherical plain bearings can accommodate a certain magnitude of axial load F_a in addition to a simultaneously acting radial load F_r (→ fig. 6 on page 41). When the resultant load is constant in magnitude, the equivalent dynamic bearing load can be calculated using

$$P = y F_r$$

where

P = equivalent dynamic bearing load [kN]

F_r = radial component of the load [kN]

y = load factor that depends on the ratio of the axial to the radial load F_a/F_r

– for bearings requiring maintenance

(→ diagram 1)

– for maintenance-free bearings

(→ diagram 2)

Diagram 1

Factor y for radial spherical plain bearings requiring maintenance

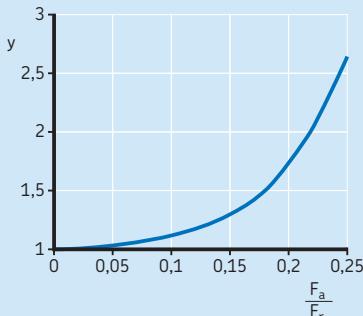

Diagram 2

Factor y for maintenance-free radial spherical plain bearings

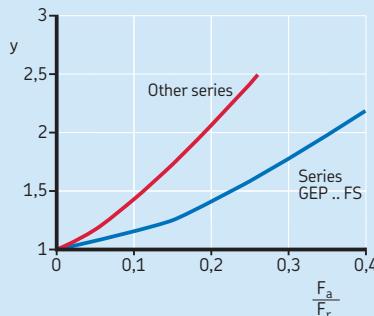

Diagram 3

Factor y for angular contact spherical plain bearings

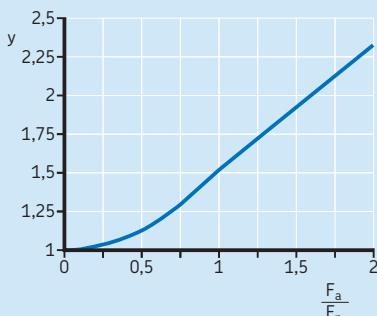

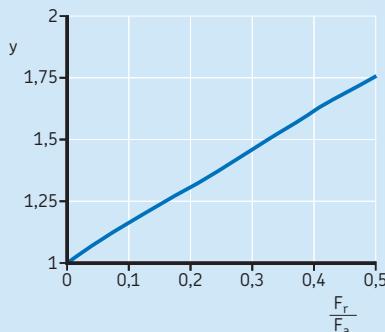

Diagram 4

Factor y for thrust spherical plain bearings

If $F_r/F_a > 2$, use a thrust spherical plain bearing instead, or contact the SKF application engineering service.

If $F_r/F_a > 0.5$, use an angular contact spherical plain bearing instead, or contact the SKF application engineering service.

Fig. 9

Angular contact spherical plain bearings
When the resultant load (\rightarrow fig. 9) is constant in magnitude, then use

$$P = y F_r$$

where

P = equivalent dynamic bearing load [kN]

F_r = radial component of the load [kN]

y = load factor that depends on the ratio of the axial to the radial load F_a/F_r (\rightarrow diagram 3)

Thrust spherical plain bearings

Thrust spherical plain bearings can accommodate a radial load F_r in addition to an axial load F_a (\rightarrow fig. 10). However, the radial load must not exceed 50% of the simultaneously acting axial load. When the resultant load is constant in magnitude, then use

$$P = y F_a$$

where

P = equivalent dynamic bearing load [kN]

F_a = axial component of the load [kN]

y = load factor depending on the ratio of the radial to the axial load F_r/F_a (\rightarrow diagram 4)

Equivalent static bearing load

If spherical plain bearings and rod ends are subjected to static loads, or very slight alignment movements, then the permissible load is not limited by wear, but by the strength of the sliding contact layer or the strength of the rod end housing.

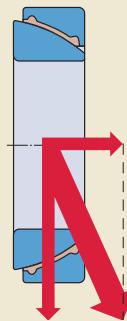

If the actual load is a combined load, then an equivalent static bearing load must be calculated. For radial and angular contact spherical plain bearings, it can be calculated using

$$P_0 = y F_r$$

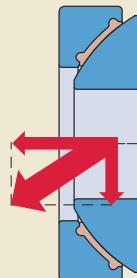

For thrust spherical plain bearings, it can be calculated using

$$P_0 = y F_a$$

Angular contact spherical plain bearing under combined load

Thrust spherical plain bearing under combined load

where

P_0 = equivalent static bearing load [kN]

F_r = radial component of the load [kN]

F_a = axial component of the load [kN]

y = load factor that depends on the ratio of the axial to the radial load F_a/F_r

- for radial bearings requiring maintenance (\rightarrow diagram 1)

- for maintenance-free radial bearings (\rightarrow diagram 2)

- for angular contact spherical plain bearings (\rightarrow diagram 3)

and load factor that depends on the ratio of the radial to the axial load F_r/F_a

- for thrust spherical plain bearings (\rightarrow diagram 4)

Permissible loads for rod ends

Rod ends are primarily intended for the support of radial loads acting in the direction of the shank axis. If loads act at angles to the shank axis (\rightarrow fig. 11), the maximum permissible load is reduced, as additional bending stresses occur in the shank. Under these conditions, consider the design and size dependent material used for the rod end housing (\rightarrow table 6 on page 170).

The load portion acting perpendicular to the direction of the shank axis should never exceed the value of $0,1 C_0$. If heavier loads are involved, a larger rod end should be selected.

The maximum permissible load for a rod end in the direction of the shank axis can be calculated using

$$P_{\text{perm}} = C_0 b_2 b_6$$

where

P_{perm} = maximum permissible load [kN]

C_0 = static load rating [kN]

b_2 = temperature factor

- for rod ends requiring maintenance (\rightarrow table 5 on page 52)
- for maintenance-free rod ends with the sliding contact surface combination
 - steel/PTFE sintered bronze (\rightarrow diagram 16 on page 55)
 - steel/PTFE fabric (\rightarrow diagram 17 on page 56)
 - steel PTFE FRP (\rightarrow diagram 19 on page 59)

b_6 = factor for the type of load (\rightarrow table 2)

Fig. 11

Rod end under combined load

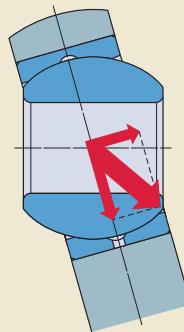

Table 2

Factor b_6 for rod end load type

Type of load	Factor b_6
Constant	1
Pulsating magnitude (single direction)	0,5 (0,35)
Alternating direction	0,5 (0,35)

The values in brackets apply to rod ends with a relubrication facility.

Requisite bearing size

To determine the requisite size of a spherical plain bearing or rod end, it is necessary to know the requisite rating life for the application. This depends on the type of machine, the operating conditions and the demands regarding operational reliability. The following steps can be used to determine requisite bearing size:

- 1 Use the guideline values of the load ratio C/P provided in **table 3** to obtain a requisite basic dynamic load rating C. Compare this value with the basic dynamic load rating of the bearings listed in the product tables.
- 2 Use **diagrams 5 to 10 on pages 46 to 50** to check whether the sliding contact surface combination of the selected bearing or rod end can be used under the actual load p and sliding velocity v conditions. The specific bearing load p and the sliding velocity v needed to perform this check can be calculated as explained in the following sections:
 - a) If the pv diagram indicates that the basic rating life equation can be used, proceed to step 3.
 - b) If the pv diagram shows that the pv range is exceeded, select a bearing with a higher load carrying capacity.
- 3 Calculate the basic rating life (\rightarrow **page 51**) and proceed as follows:
 - a) If the calculated rating life is shorter than the requisite rating life, a larger bearing or rod end should be selected and the calculation repeated.
 - b) If the calculated rating life is larger than the requisite rating life, the bearing or rod end can be selected for the application.

The bearing or rod end size is often determined by the dimensions of the associated components. In these cases, check the pv diagram to determine if the product is suitable.

GX .. F	50	80
GEP .. FS	80	120
GEC .. FBAS	80	120
Rod ends	50	80

Selection of bearing size

Specific bearing load

The magnitude of the specific bearing load can be calculated using

$$p = K \frac{P}{C}$$

where

p = specific bearing load [N/mm^2]

K = specific load factor depending on the bearing design and sliding contact surface combination (\rightarrow **table 4 on page 45**) [N/mm^2]

P = equivalent dynamic bearing load [kN]

C = basic dynamic load rating [kN]

Mean sliding velocity

The mean sliding velocity for constant movement can be calculated using

$$v = 5,82 \times 10^{-7} d_m \beta f$$

where

v = mean sliding velocity [m/s]

When the operation is intermittent (not continuous), the mean sliding velocity should be calculated for a cycle of operation

d_m = inner ring mean diameter [mm]

$d_m = d_k$ for radial spherical plain bearings and rod ends

$d_m = 0,9 d_k$ for angular contact spherical plain bearings

$d_m = 0,7 d_k$ for thrust spherical plain bearings

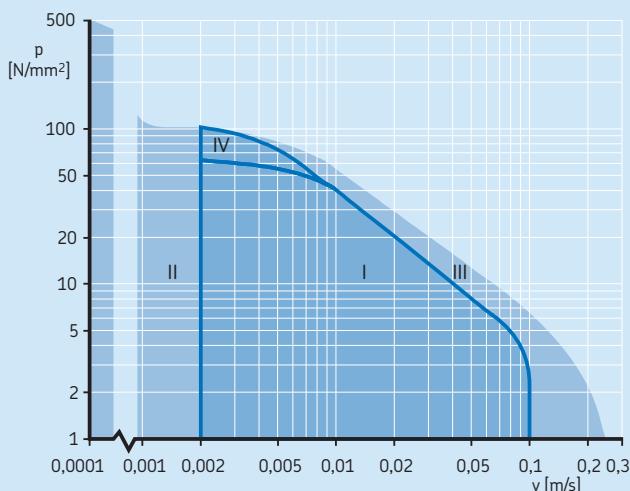

d_k = inner ring sphere diameter [mm]

β = half the angle of oscillation (\rightarrow **fig. 3 on page 39**), degrees [$^\circ$], for rotation $\beta = 90^\circ$

f = frequency of oscillation [min^{-1}], or rotational speed [min^{-1}]

Diagram 5

pv diagram for steel/steel sliding contact surface combination

Refer to Note 1 (\rightarrow **page 47**) for explanation of operating ranges.

For intermittent movement, the angle of oscillation is usually given in units of time. In this case the mean sliding velocity can be calculated using

$$v = 8,73 \times 10^{-6} d_m \frac{4\beta}{t}$$

where

β = half the angle of oscillation [°]

(→ fig. 3 on page 39)

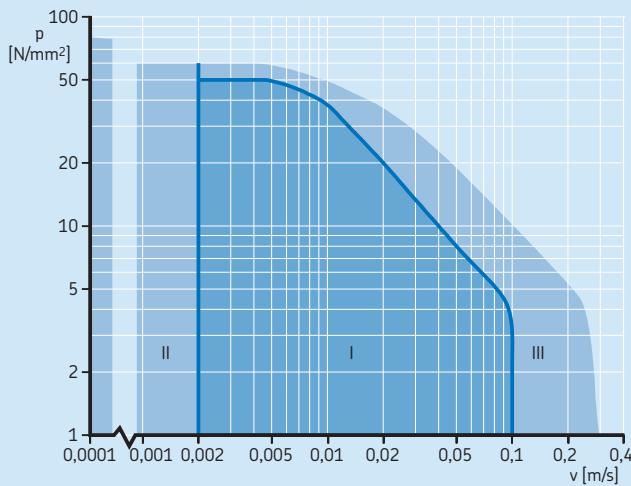

t = time taken to pass through complete oscillation [s]

NOTE 1: pv operating ranges

Basic rating life calculation

Steel/steel and steel/bronze sliding contact surface combinations, requiring maintenance

The basic rating life for initial lubrication only, can be calculated using

$$G_h = b_1 b_2 b_3 b_4 b_5 \frac{330}{p^{2.5} v}$$

When the bearing is regularly relubricated after the initial lubrication

$$G_{hN} = G_h f_\beta f_H$$

or

$$G_N = 60 f G_{hN}$$

The frequency of relubrication can be calculated using

$$H = \frac{G_h}{N}$$

where

G_h = basic rating life with initial lubrication only, operating hours [h]

G_{hN} = basic rating life with regular relubrication, operating hours [h]

G_N = basic rating life with regular relubrication, number of oscillations

H = frequency of relubrication (→ diagram 15 on page 53)

b_1 = load condition factor,

$b_1 = 1$ for constant direction load

$b_1 = 2$ for alternating direction load

b_2 = temperature factor (→ table 5 on page 52)

b_3 = sliding factor (→ diagram 11)

b_4 = velocity factor (→ diagram 12 on page 52)

b_5 = factor for angle of oscillation (→ diagram 13 on page 52), refer to Note (→ page 53)

p = specific bearing load [N/mm^2] (for values of $p < 10 \text{ N/mm}^2$ use $p = 10 \text{ N/mm}^2$)

v = mean sliding velocity [m/s]

f_β = factor depending on the angle of oscillation (→ diagram 14 on page 53), refer to Note (→ page 53)

f_H = factor depending on the frequency of relubrication (→ diagram 15 on page 53)

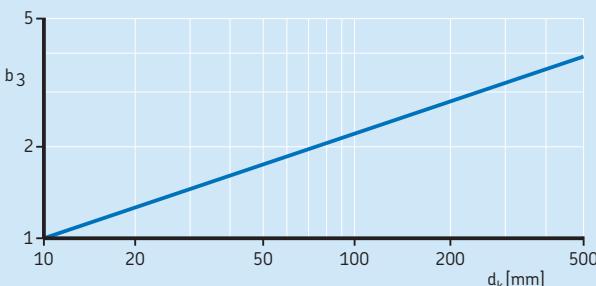

f = frequency of oscillation [min^{-1}]

N = relubrication interval [h]

If the basic rating life requirement is not met, the relubrication interval N should be shortened, or a larger bearing or rod end should be selected.

Diagram 11

Selection of bearing size

Diagram 12

Velocity factor b_4 for steel/steel and steel/bronze sliding contact surface combinations

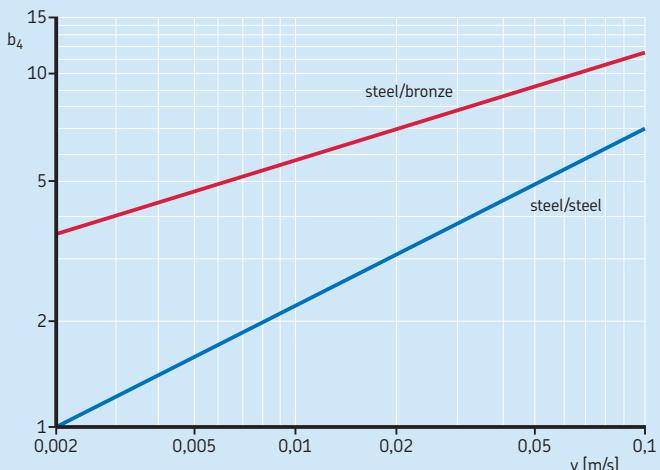

Table 5

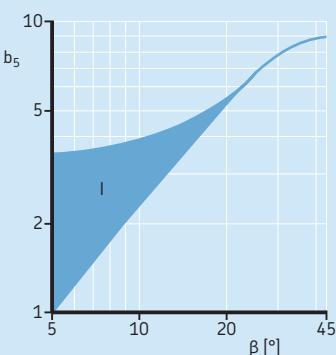

Temperature factor b_2 for steel/steel and steel/bronze sliding contact surface combinations

Operating temperature over incl.		Temperature factor b_2
°C	–	
–	120	1,0
120	160	0,9
160	180	0,8
180	–	Contact the SKF application engineering service

The temperature limits for integral seals (→ table 6 on page 79) and SKF greases (→ table 1 on page 87) must also be considered.

Diagram 13

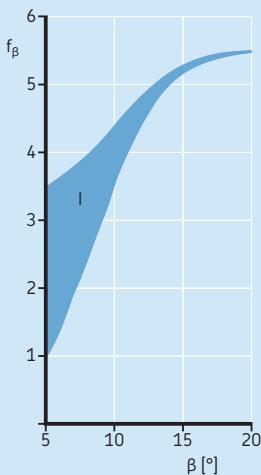

Angle of oscillation factor b_5 for steel/steel and steel/bronze sliding contact surface combinations

If $\beta < 5^\circ$, the value of b_5 for $\beta = 5^\circ$ should be used.

Diagram 14

Multiplication factor f_β for steel/steel and steel/bronze sliding contact surface combinations

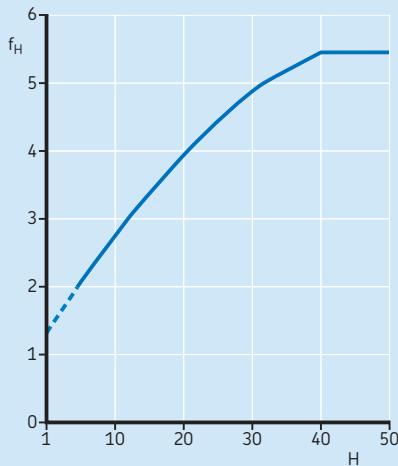

If $\beta < 5^\circ$, the value of f_β for $\beta = 5^\circ$ should be used.

NOTE: SKF manufactures all metric steel/steel radial spherical plain bearings with an outside diameter $D \geq 150$ mm as standard with the multi-groove feature in the outer ring (\rightarrow page 17). The extra large grease reservoir in the bearing, made possible by the multi-groove system, extends relubrication intervals and bearing service life, especially in applications where there are constant direction loads (\rightarrow page 40).

These advantages are considered in the calculation of the basic rating life by the coloured regions in diagrams 13 and 14 for the factors for the angle of oscillation b_5 and f_β . The values of these two factors in the upper limit of the coloured area may be used for bearings with the multi-groove system.

Diagram 15

Relubrication factor f_H for steel/steel and steel/bronze sliding contact surface combinations

If $H < 5$, the values indicated by the broken line can be used.

Selection of bearing size

Maintenance-free steel/PTFE sintered bronze sliding contact surface combination

The basic rating life can be calculated using

$$G_h = b_1 b_2 \frac{1400}{p^{1.3} v}$$

or

$$G = 60 f G_h$$

where

G_h = basic rating life, operating hours

G = basic rating life, number of oscillations

b_1 = load condition factor (\rightarrow table 6)

b_2 = temperature factor (\rightarrow diagram 16)

p = specific bearing load [N/mm^2]

v = mean sliding velocity [m/s]

f = frequency of oscillation [min^{-1}]

NOTE: Basic rating life calculations consider the influence of the load and sliding velocity. Under very light loads and/or low sliding velocities, the result shows relatively long life. The longer the service life the more important is the influence of contaminants such as dirt, moisture and corrosion. Depending on the operating conditions, accurate life calculations may not be possible.

Table 6

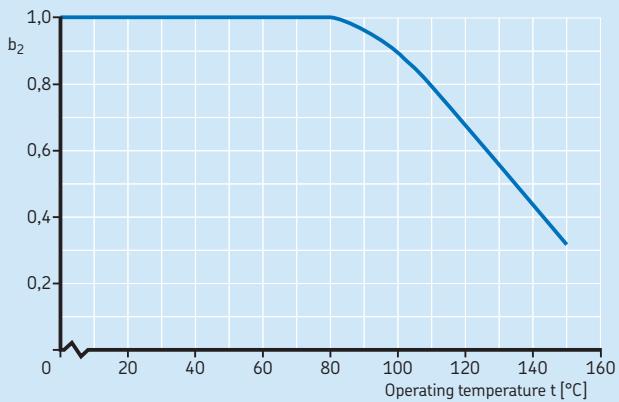

Load condition factor b_1 for the steel/PTFE sintered bronze sliding contact surface combination

Type of load	Factor b_1	Permissible specific bearing load ¹⁾ N/mm^2
—	—	
Constant load²⁾		
Single direction	1	up to 100
Variable load		
Alternating direction or pulsating magnitude at a frequency up to 0,5 Hz	0,4	up to 60
over 0,5 up to 5 Hz	0,2	up to 40

¹⁾ Inertia forces should also be taken into consideration.

²⁾ For constant load, oscillating frequencies above 300 min^{-1} and very short sliding distances, $b_1 = 1$ cannot be used because of possible material fatigue. For additional information, contact the SKF application engineering service.

Temperature factor b_2 for the steel/PTFE sintered bronze sliding contact surface combination

Selection of bearing size

Maintenance-free steel/PTFE fabric sliding contact surface combination

The basic rating life can be calculated using

$$G_h = b_1 b_2 b_4 \frac{K_p}{p^n v}$$

or

$$G = 60 f G_h$$

where

G_h = basic rating life, operating hours

G = basic rating life, number of oscillations

b_1 = load condition factor (\rightarrow **table 7**)

b_2 = temperature factor (\rightarrow **diagram 17**)

b_4 = velocity factor (\rightarrow **diagram 18 on page 58**)

K_p = constant for the specific bearing load
(\rightarrow **table 8**)

p = specific bearing load [N/mm^2]

n = exponent for the specific bearing load
(\rightarrow **table 8**)

v = mean sliding velocity [m/s]

f = frequency of oscillation [min^{-1}]

NOTE: Basic rating life calculations consider the influence of the load and sliding velocity. Under very light loads and/or low sliding velocities, the result shows relatively long life. The longer the service life the more important is the influence of contaminants such as dirt, moisture and corrosion. Depending on the operating conditions, accurate life calculations may not be possible.

Diagram 17

Temperature factor b_2 for steel/PTFE fabric sliding contact surface combination

Variable load and sliding velocity

If the load and/or sliding velocity change during operation, calculate individual rating lives for the periods of constant load and sliding velocity. If the load and sliding velocity occur as shown in **diagram 20a**, the individual basic rating life can be calculated using the constant values of p and v . If the load and sliding velocity are not constant as shown in **diagram 20b**, first calculate the basic rating life for the individual time periods, using mean values for the load and sliding velocity for the individual time periods. Then calculate the total basic rating life using

$$G_h = \frac{1}{\frac{t_1}{T G_{h1}} + \frac{t_{II}}{T G_{hII}} + \frac{t_{III}}{T G_{hIII}} + \dots}$$

where

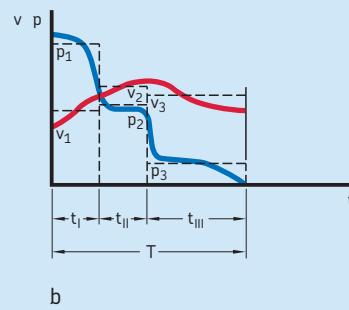

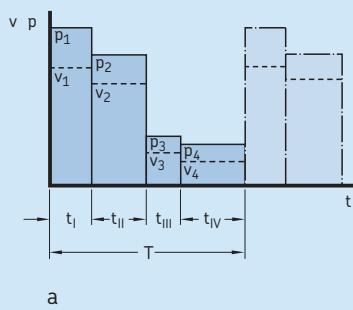

G_h = total basic rating life, operating hours
 t_1, t_{II}, \dots = time during which p_1 and v_1, p_2 and v_2 etc. pertain [h]

T = total duration of one cycle
 $(= t_1 + t_{II} + t_{III} + \dots)$ [h]

G_{hI}, \dots = individual values of basic rating life for conditions p_1 and v_1, p_2 and v_2 etc., operating hours

Diagram 20

Alternating load and variable sliding velocity

Calculation examples

The following calculation examples illustrate the methods used to determine the requisite bearing size or the basic rating life for spherical plain bearings and rod ends.

1. Torque support of a concrete transporter

Given data

Purely radial load that alternates direction:

$$F_r = 12 \text{ kN}$$

Half angle of oscillation: $\beta = 15^\circ$

(→ fig. 3 on page 39)

Frequency of oscillation: $f = 10 \text{ min}^{-1}$

Maximum operating temperature: $+80^\circ\text{C}$

Requirements

The bearing must have a basic rating life of 7 000 h.

Calculations and selection

Because a bearing in this application must accommodate an alternating load, a steel/steel radial spherical plain bearing is the appropriate choice. Relubrication is planned after every 40 hours of operation.

If, for the first check, a guideline value of 2 is used for the load ratio C/P (→ table 3 on page 45), the required basic dynamic load rating C for the bearing is

$$C = 2 P = 24 \text{ kN}$$

Bearing GE 20 ES, with a $C = 30 \text{ kN}$ and a sphere diameter $d_k = 29 \text{ mm}$, is chosen from the product table on page 104.

To check the suitability of the bearing using the pv diagram (→ diagram 5 on page 46), calculate the specific bearing load using $K = 100$ from table 4 on page 45.

$$p = K \frac{P}{C} = 100 \times \frac{12}{30} = 40 \text{ N/mm}^2$$

and the sliding velocity v using $d_m = d_k = 29 \text{ mm}$, $\beta = 15^\circ$ and $f = 10 \text{ min}^{-1}$

$$v = 5,82 \times 10^{-7} d_m \beta f$$

$$= 5,82 \times 10^{-7} \times 29 \times 15 \times 10 = 0,0025 \text{ m/s}$$

The values for p and v lie within the permissible operating range I of the pv diagram (→ diagram 5 on page 46), for steel/steel radial spherical plain bearings. To calculate the basic rating life for initial lubrication, the values that apply are

$$b_1 = 2 \text{ (alternating direction load)}$$

$$b_2 = 1 \text{ (operating temperature } < 120^\circ\text{C)} \\ \text{from table 5 on page 52)}$$

$$b_3 = 1,5 \text{ (from diagram 11 on page 51,} \\ \text{for } d_k = 29 \text{ mm)}$$

$$b_4 = 1,1 \text{ (from diagram 12 on page 52,} \\ \text{for } v = 0,0025 \text{ m/s)}$$

$$b_5 = 3,7 \text{ (from diagram 13 on page 52,} \\ \text{for } \beta = 15^\circ)$$

$$p = 40 \text{ N/mm}^2$$

$$v = 0,0025 \text{ m/s}$$

Therefore

$$G_h = b_1 b_2 b_3 b_4 b_5 \frac{330}{p^{2,5} v}$$

$$= 2 \times 1 \times 1,5 \times 1,1 \times 3,7 \times \frac{330}{40^{2,5} \times 0,0025}$$

$$\approx 160 \text{ operating hours}$$

The basic rating life of the bearing that is relubricated regularly can now be calculated using

$$f_B = 5,2 \text{ (from diagram 14 on page 53)}$$

$$f_H = 1,8 \text{ (from diagram 15 on page 53, for a} \\ \text{relubrication frequency } H = G_h/N = 160/40 \\ = 4 \text{ with the relubrication interval of 40 h)}$$

$$G_{hN} = G_h f_B f_H = 160 \times 5,2 \times 1,8$$

$$\approx 1 500 \text{ operating hours}$$

Because this life is shorter than the required rating life of 7 000 h, a larger bearing is chosen and calculations are repeated.

Bearing GE 25 ES, with $C = 48 \text{ kN}$ and $d_k = 35,5 \text{ mm}$, is chosen. The values for the specific bearing load lie within the permissible operating range I of the pv diagram (→ **diagram 5** on **page 46**)

$$p = 100 \times \frac{12}{48} = 25 \text{ N/mm}^2$$

and the sliding velocity is

$$v = 5,82 \times 10^{-7} \times 35,5 \times 15 \times 10 = 0,0031 \text{ m/s}$$

As before

$$b_1 = 2, b_2 = 1, b_5 = 3,7$$

and now

$$b_3 = 1,6 \text{ (from } \mathbf{diagram 11 \text{ on page 51}, \\ \text{for } d_k = 35,5 \text{ mm})$$

$$b_4 = 1,2 \text{ (from } \mathbf{diagram 12 \text{ on page 52}}, \\ \text{for } v = 0,0031 \text{ m/s})$$

Therefore, the basic rating life for initial lubrication is

$$G_h = 2 \times 1 \times 1,6 \times 1,2 \times 3,7 \times \frac{330}{25^{2,5} \times 0,0031}$$

≈ 480 operating hours

With $f_B = 5,2$ (from **diagram 14** on **page 53**) and $f_H = 3$ (from **diagram 15** on **page 53** for $H = 480/40 = 12$) the basic rating life for regular relubrication ($N = 40 \text{ h}$) becomes

$$G_{hN} = 480 \times 5,2 \times 3 \approx 7\,490 \text{ operating hours}$$

This larger bearing satisfies the rating life requirement.

NOTE: The *SKF Interactive Engineering Catalogue* incorporates programs to perform these and many other calculations quickly and accurately. These programs can be run any number of times to find the best possible solution.

The *SKF Interactive Engineering Catalogue* is available online at www.skf.com.

Selection of bearing size

2. Attachment of a shock absorber of an off-highway vehicle

Given data:

Radial load: $F_r = 7 \text{ kN}$

Axial load: $F_a = 0,7 \text{ kN}$

Half angle of oscillation: $\beta = 8^\circ$ (\rightarrow fig. 3 on page 39)

Frequency of oscillation: $f = 15 \text{ min}^{-1}$

Load frequency: 2–5 Hz

Maximum operating temperature: $+75^\circ\text{C}$

Requirements:

This bearing must have a basic rating life corresponding to a driven distance of 100 000 km at an average speed of 65 km/h without maintenance.

Calculations and selection

For design reasons, a GE 20 C spherical plain bearing with a steel/PTFE sintered bronze sliding contact surface combination is proposed.

From the product table on page 132, the basic dynamic load rating $C = 31,5 \text{ kN}$ and the sphere diameter $d_k = 29 \text{ mm}$ are obtained.

First, the equivalent dynamic bearing load must be determined by

$$F_a/F_r = 0,7/7 = 0,1$$

From diagram 2 on page 42 factor $y = 1,4$. The equivalent dynamic bearing load is therefore

$$P = y F_r = 1,4 \times 7 = 9,8 \text{ kN}$$

To check the suitability of the bearing size using the pv diagram 7 on page 48, calculate the values for the specific bearing load (using $K = 100$ from table 4 on page 45) using

$$p = K \frac{P}{C} = 100 \times \frac{9,8}{31,5} = 31 \text{ N/mm}^2$$

and the sliding velocity ($d_m = d_k = 29 \text{ mm}$).

$$v = 5,82 \times 10^{-7} \text{ dm } \beta f$$

$$= 5,82 \times 10^{-7} \times 29 \times 8 \times 15 = 0,002 \text{ m/s}$$

The values for p and v lie within the permissible operating range l of the pv diagram where

$$b_1 = 0,2 \text{ (from table 6 on page 54, for a load frequency over } 0,5 \text{ Hz and } 25 < p < 40 \text{ N/mm}^2)$$

$$b_2 = 1 \text{ (from diagram 16 on page 55, for temperatures } < 80^\circ\text{C})$$

The basic rating life for a GE 20 C bearing with the steel/PTFE sintered bronze sliding contact surface combination is

$$\begin{aligned} G_h &= b_1 b_2 \frac{1400}{p^{1,3} v} \\ &= 0,2 \times 1 \times \frac{1400}{31^{1,3} \times 0,002} \\ &\approx 1600 \text{ operating hours} \end{aligned}$$

This basic rating life corresponds to a distance (at an average speed of 65 km/h) of $1600 \times 65 = 104 000 \text{ km}$. Therefore, the bearing satisfies the rating life requirement.

3. A 320-bar hydraulic cylinder on a fully automatic press for building industry waste

Given data

Radial load (constant direction)

Operation case	Load F_r	Time period t
I	300 kN	10%
II	180 kN	40%
III	120 kN	50%

The number of press cycles $n = 30$ per hour, and the movement between the end positions (90°) is made in 10 seconds. The operating temperature is less than $+50^\circ\text{C}$.

Requirements

A maintenance-free radial spherical plain bearing with a steel/PTFE fabric sliding contact surface combination is required for a rating life of 5 years with 70 h of operation per week.

Calculations and selection

Using a guideline value for the load ratio $C/P = 2$ (→ **table 3 on page 45**), and with $P = F_{rl}$ the required basic dynamic load rating

$$C = 2P = 2 \times 300 = 600 \text{ kN}$$

From the product **table on page 136**, a GE 60 TXE-2LS bearing with a basic dynamic load rating $C = 695 \text{ kN}$ and a sphere diameter $d_k = d_m = 80 \text{ mm}$ is chosen.

First, it is necessary to check that the operation cases I to III fall within the permissible range of the **pv diagram 8 on page 49**.

The sliding velocity is the same for all three cases. The angle of oscillation is specified as 2β , the time t as the time taken to pass through 2β in seconds. Complete cycle duration is 4β (→ **fig 3 on page 39**).

$$v = 8,73 \times 10^{-6} d_m \frac{2\beta}{t}$$

$$= 8,73 \times 10^{-6} \times 80 \times \frac{90}{10} = 0,0063 \text{ m/s}$$

The specific bearing load, $p = K(P/C)$, using $K = 300$ from **table 4 on page 45**, is

for case I

$$p_I = K \frac{P}{C} = 300 \times \frac{300}{695} = 129,5 \text{ N/mm}^2$$

for case II

$$p_{II} = K \frac{P}{C} = 300 \times \frac{180}{695} = 77,7 \text{ N/mm}^2$$

for case III

$$p_{III} = K \frac{P}{C} = 300 \times \frac{120}{695} = 51,8 \text{ N/mm}^2$$

The values for p_I , p_{II} , p_{III} and v are within the permissible range I of the **pv diagram 8 on page 49**.

To make the lifetime estimate for variable loads and/or sliding velocities, the calculation of each load case has to be made separately, with the equation for TX bearings first

$$G_h = b_1 b_2 b_4 \frac{K_p}{p^n v}$$

The parameters b_1 , b_2 , b_4 , K_p and n are defined on **page 56** and are as follows

$b_1 = 1$ (from **table 7 on page 57**, constant load)
 $b_2 = 1$ (from **diagram 17 on page 56**, operating temperature $< +50^\circ\text{C}$)

$b_4 =$ (from **diagram 18 on page 58**)

$$b_{4I} = 0,31$$

$$b_{4II} = 0,48$$

$$b_{4III} = 0,57$$

$K_p =$ (from **table 8 on page 57**)

$$K_{pI} = 40\,000$$

$$K_{pII} = 4\,000$$

$$K_{pIII} = 4\,000$$

$n =$ (from **table 8 on page 57**)

$$n_1 = 1,2$$

$$n_2 = 0,7$$

$$n_3 = 0,7$$

Selection of bearing size

for case I

$$G_{hI} = 1 \times 1 \times 0,31 \times \frac{40\,000}{129,5^{1,2} \times 0,0063}$$

$$= 5\,745 \text{ operating hours}$$

for case II

$$G_{hII} = 1 \times 1 \times 0,48 \times \frac{4\,000}{77,7^{0,7} \times 0,0063}$$

$$= 14\,477 \text{ operating hours}$$

for case III

$$G_{hIII} = 1 \times 1 \times 0,57 \times \frac{4\,000}{51,8^{0,7} \times 0,0063}$$

$$= 22\,833 \text{ operating hours}$$

Using the calculated basic rating lives of the three operation cases, the total basic rating life for continuous operation is (\rightarrow page 61)

$$G_h = \frac{1}{\frac{t_I}{T G_{hI}} + \frac{t_{II}}{T G_{hII}} + \frac{t_{III}}{T G_{hIII}}}$$

For t_I , t_{II} etc., the percentages given in the operating data are inserted (with $T = t_I + t_{II} + t_{III} = 100\%$.)

$$G_h = \frac{1}{\frac{10}{100 \times 5\,745} + \frac{40}{100 \times 14\,477} + \frac{50}{100 \times 22\,833}}$$

$$\approx 14\,940 \text{ operating hours}$$

The required life of five years should be met assuming the machine is operated 70 h/week, 30 cycles/hour and 50 weeks per year, to 525 000 cycles or 2 916 operating hours. (Note that time for a complete cycle is 20 s.)

$$G_{N,\text{Req}} = 5 \times 70 \times 30 \times 50 = 525\,000 \text{ cycles}$$

$$G_{h,\text{Req}} = (525\,000 \times 20) / 3600 = 2\,916 \text{ h.}$$

4. Linkages of a conveyor installation

Given data

Radial load of alternating direction: $F_r = 5,5 \text{ kN}$
 Half angle of oscillation: $\beta = 15^\circ$ (\rightarrow fig. 3 on page 39)
 Frequency of oscillation: $f = 25 \text{ min}^{-1}$
 Operating temperature: $+70^\circ\text{C}$

Requirements

A rod end is needed that provides a basic rating life of 9 000 hours under alternating load conditions.

Calculations and selection

Because the load is alternating, a steel/steel rod end is appropriate. Relubrication is planned every 40 hours of operation. Using the guideline value for the load ratio $C/P = 2$ from table 3 on page 45, and as $P = F_r$, the requisite basic dynamic load rating is

$$C = 2P = 2 \times 5,5 = 11 \text{ kN}$$

The SI 15 ES rod end with a basic dynamic load rating $C = 17 \text{ kN}$ is selected (\rightarrow page 172). The basic static load rating is $C_0 = 37,5 \text{ kN}$ and the sphere diameter $d_k = 22 \text{ mm}$.

To check the suitability of rod end size using the pv diagram 5 on page 46, calculate the values for the specific bearing load (using $K = 100$ from table 4 on page 45)

$$p = K \frac{P}{C} = 100 \times \frac{300}{695} = 32,4 \text{ N/mm}^2$$

and the mean sliding velocity ($d_m = d_k = 22 \text{ mm}$)

$$v = 5,82 \times 10^{-7} d_k \beta f$$

$$= 5,82 \times 10^{-7} \times 22 \times 15 \times 25 = 0,0048 \text{ m/s}$$

The values for p and v lie within the permissible range I of the pv diagram 5 on page 46.

Checking the permissible load on the rod end housing

$$\begin{aligned} C_0 &= 37,5 \text{ kN} \\ b_2 &= 1 \text{ (from table 5 on page 52, for temperatures } < 120^\circ\text{C)} \\ b_6 &= 0,35 \text{ (from table 2 on page 44, for rod ends with a lubrication hole)} \\ P_{\text{perm}} &= C_0 b_2 b_6 \end{aligned}$$

$$= 37,5 \times 1 \times 0,35$$

$$= 13,125 \text{ kN} > P$$

The following values of the factors are used to determine the basic rating life for initial lubrication only

$$\begin{aligned} b_1 &= 2 \text{ (alternating load)} \\ b_2 &= 1 \text{ (for operating temperatures } < 120^\circ\text{C, from table 5 on page 52)} \\ b_3 &= 1,3 \text{ (from diagram 11 on page 51, for } d_k = 22 \text{ mm)} \\ b_4 &= 1,6 \text{ (from diagram 12 on page 52, for } v = 0,0048 \text{ m/s)} \\ b_5 &= 3,7 \text{ (from diagram 13 on page 52, for } \beta = 15^\circ) \\ p &= 32 \text{ N/mm}^2 \\ v &= 0,0048 \text{ m/s} \end{aligned}$$

Therefore

$$G_h = b_1 b_2 b_3 b_4 b_5 \frac{330}{32,4^{2,5} \times 0,0048}$$

$$= 2 \times 1 \times 1,3 \times 1,6 \times 3,7 \times \frac{330}{32,4^{2,5} \times 0,0048}$$

$$\approx 177 \text{ operating hours}$$

The basic rating life for regular relubrication ($N = 40 \text{ h}$) with

$$\begin{aligned} f_\beta &= 5,2 \text{ (from diagram 14 on page 53) and} \\ f_H &= 2 \text{ (from diagram 15 on page 53, for } H = G_h/N = 177/40 = 4,4) \\ G_{hN} &= G_h f_b f_H = 177 \times 5,2 \times 2 \end{aligned}$$

$$\approx 1840 \text{ operating hours}$$

Selection of bearing size

The required basic rating life of 9 000 h is not achieved; therefore a larger rod end has to be selected. A SI 20 ES rod end, with $C = 30 \text{ kN}$, $C_0 = 57 \text{ kN}$ and $d_k = 29 \text{ mm}$ is selected and the calculation repeated.

The values for the specific bearing load

$$p = K \frac{P}{C} = 100 \times \frac{5,5}{30} = 18,3 \text{ N/mm}^2$$

and the mean sliding velocity ($d_m = d_k = 29 \text{ mm}$)

$$v = 5,82 \times 10^{-7} \times 29 \times 15 \times 25 = 0,0063 \text{ m/s}$$

both lie within the permissible range I. It is not necessary to check the permissible rod end housing load since the basic static load rating of the larger rod end is higher. Also, as before

$$b_1 = 2; b_2 = 1 \text{ and } b_5 = 3,7$$

while

$b_3 = 1,4$ (from **diagram 11 on page 51**,
for $d_k = 29 \text{ mm}$)

$b_4 = 1,8$ (from **diagram 12 on page 52**,
for $v = 0,0063 \text{ m/s}$)

so that

$$G_h = 2 \times 1 \times 1,4 \times 1,8 \times 3,7 \times \frac{330}{18,3^{2,5} \times 0,0063}$$

$$\approx 681 \text{ operating hours}$$

With $f_B = 5,2$ (from **diagram 14 on page 53**) and $f_H = 3,7$ (from **diagram 15 on page 53**, for $H = 681/40 \approx 17$) the basic rating life for regular relubrication ($N = 40 \text{ h}$) becomes

$$G_{hN} = 681 \times 5,2 \times 3,7$$

$$\approx 13\,100 \text{ operating hours}$$

Therefore, the larger rod end meets the rating life requirements.

Friction

The friction in a spherical plain bearing or rod end depends primarily on the sliding contact surface combination, the load and the sliding velocity. Because there are so many influencing factors that are not mutually independent, it is not possible to quote exact values for the coefficient of friction. Under laboratory conditions, however, it is possible to record the coefficient of friction for different sliding contact surface combinations. The friction during the running-in phase is higher than the value recorded during the subsequent test period.

Guideline values for the coefficient of friction μ are listed in **table 1**. They have been determined in laboratory trials.

The coefficient of friction for maintenance-free steel/PTFE fabric and steel/PTFE sintered bronze sliding contact surface combinations decrease with increasing specific load. At a constant specific load, friction is reduced to the given minimum value as soon as the transfer of PTFE from the sliding layer to the opposing steel surface is complete. The frictional moment for a spherical plain bearing or rod end can be calculated using

$$M = 0,5 \mu P d_m$$

where

M = frictional moment [Nm]

μ = coefficient of friction (\rightarrow **table 1**)

P = equivalent dynamic bearing load [kN]

d_m = inner ring mean diameter [mm]

$d_m = d_k$ for radial spherical plain bearings and rod ends

$d_m = 0,9 d_k$ for angular contact spherical plain bearings

$d_m = 0,7 d_k$ for thrust spherical plain bearings

d_k = inner ring sphere diameter [mm]

Table 1

Coefficient of friction for different sliding contact surface combinations (guideline values)

Sliding contact surface combination	Coefficient of friction μ	min	max
Steel/steel	0,08	0,20	
Steel/bronze	0,10	0,25	
Steel/PTFE sintered bronze	0,05	0,25	
Steel/PTFE fabric	0,02	0,15	
Steel/PTFE FRP	0,05	0,20	

After the bearing has been in operation for an extended period of time, negative influences (contamination, inadequate lubrication) may cause the bearing to approach or exceed the maximum values for the coefficient of friction listed in the table. Bearings are susceptible to this phenomenon even under light loads and especially under harsh operating conditions. In applications where friction is particularly important, SKF recommends determining the power ratings by using the maximum values for the coefficient of friction that are listed in **table 1**. For bearings operating under conditions of mixed or dry friction, there may be slight differences between adhesive and sliding friction. Experience has shown that it is not possible to eliminate stick-slip entirely and that it most frequently occurs when support elements lack adequate stiffness. In most applications, however, the effects are negligible.

Design of bearing arrangements

Radial location of bearings

The inner and outer rings of spherical plain bearings must be radially secured (located) to the shaft and in the housing so that sliding movements occur in the bearing and do not result in ring creep. Ring creep occurs when a ring turns on its seat in the circumferential direction under load. To locate a bearing in the radial direction usually requires an interference fit. However, an interference fit cannot always be applied, e.g. if easy mounting and dismounting are required, or if the bearing must be able to be displaced axially without restraint.

The appropriate fit is always determined by the operating conditions.

1. Type and magnitude of the load

The degree of interference must suit the type and magnitude of the load, i.e. the heavier the load and the stronger the shock loads, the tighter the interference required (**→ fig. 1**).

- Under heavy loads, spherical plain bearings deform elastically, which may affect the interference fit and lead to ring creep.
- The strength of the associated components must be adequate to accommodate the loads and fully support the bearing.
- If the associated components deform, there is a risk that through-hardened bearing rings crack.
- Steel/steel radial spherical plain bearings require a tighter fit than comparable maintenance-free bearings, which have a lower coefficient of friction.

2. Bearing internal clearance

An interference fit on the shaft and in the housing causes the inner ring to expand elastically, and the outer ring to be compressed elastically.

This reduces the initial internal clearance in the bearing, prior to operation. The operating clearance (**→ fig. 2**) furthermore takes the load and operating temperature into consideration.

The initial radial internal clearance of bearings differs, depending on the type and size of the bearing. The clearance has been selected so that if the recommended tolerances for the shaft and housing seats are applied, an appropriate operating clearance (or preload) remains in the bearing under normal operating conditions.

If a tight interference fit is used for both bearing rings, or if the operating temperatures are unusual, it may be necessary to use a larger initial internal clearance than "Normal" for steel/steel bearings.

3. Temperature conditions

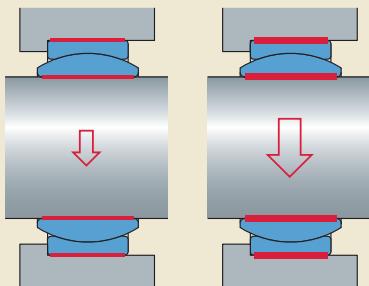

In operation, the bearing rings normally have a higher temperature than their seats. This means that

- the inner ring fit gets loosen (**→ fig. 3**)
- the outer ring fit becomes tighter and may restrict any required axial displacement in the housing.

If there is a considerable temperature difference between the inner ring and outer ring, there is a change in the operating clearance. This condition must be considered when selecting the fit or the bearing could seize, making it difficult or impossible for the shaft to turn.

Fig. 1

For heavier loads a tighter interference fit is needed

4. Design of associated components

The bearing seats on the shaft and in the housing must not lead to uneven distortion (out-of-round) of the bearing rings (\rightarrow fig. 4). Therefore:

- Split housings are not suitable for interference fits.
- Thin-walled housings, light alloy housings and hollow shafts require a tighter fit than thick-walled steel or cast iron housings and solid shafts – and must have sufficient strength.
- Heavy loads and interference fits require thick-walled one-piece steel or cast iron housings and solid steel shafts.

Fig. 2

Reduction of the clearance in the bearing

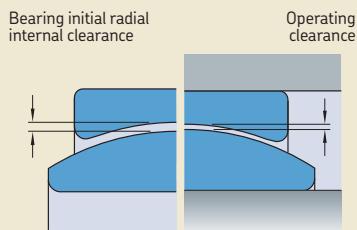

Fig. 3

Change to the fit with temperature

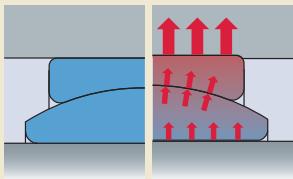

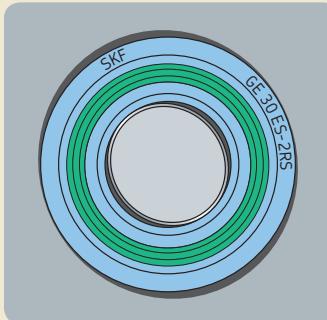

Fig. 4

Out-of-round bearing seat

Design of bearing arrangements

5. Axial displacement of non-locating bearings
A non-locating bearing provides radial support only and must always be able to be displaced axially (→ fig. 5). This is normally achieved by selecting a loose fit for one of the bearing rings, generally the inner ring of a spherical plain bearing. Reasons include the following:

- The shaft seat can be easily and economically hardened and ground to facilitate axial displacement. The hardness of the shaft should be at least 50 HRC.
- The outer rings of most spherical plain bearings are axially fractured at one or two positions, or are radially split. This can make axial displacement difficult, if not impossible.
- The housing bore should be protected against wear.

Surface finish of seats

The recommended surface roughness for bearing seats is in accordance with ISO 4288:1997.

- for shaft seats $R_z \leq 10 \mu\text{m}$
- for housing bore seats $R_z \leq 16 \mu\text{m}$

Recommended fits

Only a limited number of ISO tolerance classes are appropriate for spherical plain bearings.

Fig. 6 shows schematically the relative positions of these in relation to the bore and outside diameter of the bearings. The recommended tolerance classes for

- the shaft seat are provided in **table 1**
- the housing bore are provided in **table 2**

These recommendations are based on the considerations described above and have been confirmed in a wide variety of bearing applications. The ISO tolerance limits are listed in

- **table 3 on page 74** for shafts
- **table 4 on page 74** for housing bores

To facilitate the calculation of the minimum and maximum values of the theoretical interference or clearance, the standardized bearing bore diameter deviations (Δ_{dmp}) and the bearing outside diameter deviations (Δ_{Dmp}) are listed in **tables 3 and 4**.

Fig. 5

Axial displacement

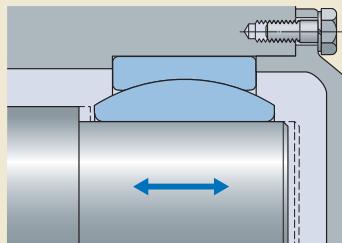

Fig. 6

ISO shaft and housing tolerance classes

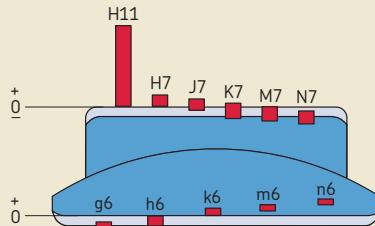

Table 1

Shaft fits		
Operating conditions	Tolerance classes Sliding contact surface combination	
	steel/steel and steel/bronze	steel/PTFE sintered bronze, steel/PTFE fabric and steel/PTFE FRP
Radial spherical plain bearings Loads of all kinds, interference fit	m6 (n6) ¹⁾	k6
Loads of all kinds, clearance or transition fit	h6 (hardened shaft)	h6 or g6 (hardened shaft)
Angular contact spherical plain bearings Loads of all kinds, interference fit	m6 (n6)	m6
Thrust spherical plain bearings Loads of all kinds, interference fit	m6 (n6)	m6

The tolerance classes in brackets should be selected for very heavily loaded bearings. If selected, be sure that the residual operating clearance is sufficient for proper performance of the bearing or whether a bearing with larger clearance must be used.

¹⁾ These recommendations do not apply to bearings in the GEG series, which have a bore diameter tolerance class to H7 and are normally mounted on shaft seats machined to tolerance class m7. If, for mounting reasons, the shaft is machined to tolerance class f7, it should be hardened as movements of the shaft relative to the bearing bore take place and wear may result.

Table 2

Housing fits		
Operating conditions	Tolerance classes Sliding contact surface combination	
	steel/steel	steel/PTFE sintered bronze, steel/PTFE fabric and steel/PTFE FRP
Radial spherical plain bearings Light loads, axial displacement required	H7	H7
Heavy loads	M7 (N7)	K7
Light alloy housings	N7	M7
Angular contact spherical plain bearings Loads of all kinds, interference fit	M7 (N7)	M7
Loads of all kinds, can generally be displaced axially	J7	J7
Thrust spherical plain bearings Purely axial loads	H11	H11
Combined loads	J7	J7

The tolerance classes in brackets should be selected for very heavily loaded bearings. If selected, be sure that the residual operating clearance of the radial bearing is sufficient for proper performance or whether a bearing with larger clearance must be used.

Axial location of bearings

Locating bearings

An interference fit alone is not sufficient to axially locate a bearing ring. It is usually necessary to use a suitable locking device to secure the ring in place.

Both rings of a locating bearing should be located axially on both sides. The bearing rings generally have an interference fit and are usually supported on one side by a shaft or housing shoulder. Inner rings are axially secured on the opposite end by

- a plate bolted to the shaft end (→ fig. 7)
- a spacer sleeve between the ring and a neighbouring machine component (→ fig. 8)
- a retaining ring (circlip)

Outer rings are generally retained by the cover of the housing bore (→ figs. 7 and 8).

Non-locating bearings

For non-locating bearings, the outer ring (which normally has a tight fit) is axially located while the inner ring is free to move axially on the shaft (→ fig. 5 on page 72).

Note that for bearings in the GEP series (→ fig. 9), which have a radially split outer ring, expansion forces are produced under purely radial load; the axial components of these forces act on the housing cover. The axial load acting on the cover may be as much as 30% of the radial load. This must be taken into account when

Fig. 7

Using a spacer sleeve and cover to locate a bearing axially

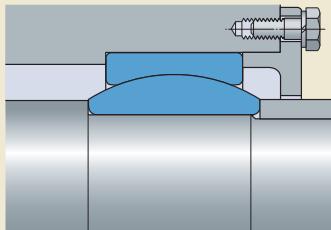

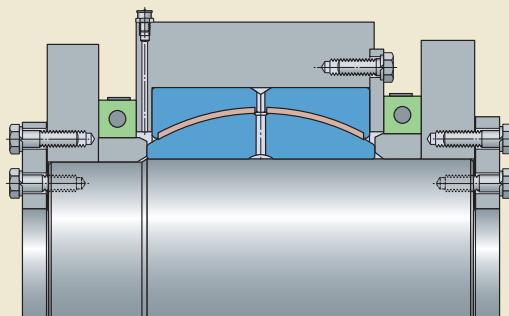

Fig. 9

Locating a radial spherical plain bearing having a radially split outer ring

Design of bearing arrangements

dimensioning the housing cover and selecting the size and number of the attachment bolts.

If shaft and/or housing shoulders are undesirable because of manufacturing or assembly considerations, spacer sleeves or rings can be inserted between a bearing ring and an adjacent machine component (→ figs. 10 and 11).

Axially locating a non-separable bearing with locating rings (→ figs. 10 and 11) saves space, enables quick mounting and dismounting and simplifies the machining of the seats. If larger axial forces have to be accommodated, a support ring (→ fig. 11) should be placed between the bearing ring and the locating ring, so that the locating ring is not subjected to excessive bending moments.

To locate the bearing, retaining rings (also known as circlips) with a constant radial width in accordance with DIN 471:1981 or DIN 472:1981 can be used.

Fig. 10

Locating a bearing axially, using retaining rings in the housing and adjacent components on the shaft

Locating a bearing axially, using adjacent components in the housing and a support ring and a retaining ring on the shaft

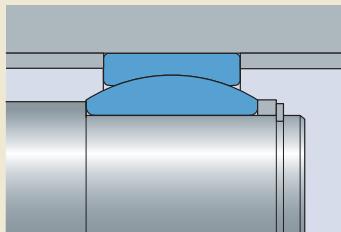

Fig. 12

Shaft and housing abutment dimensions

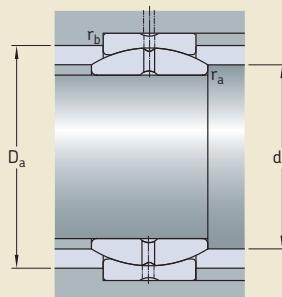

Fig. 13

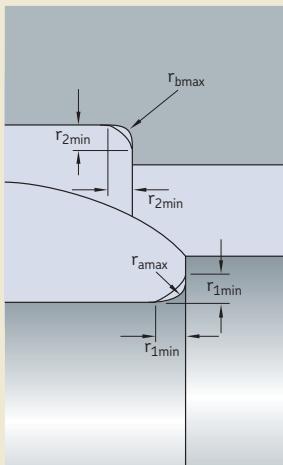

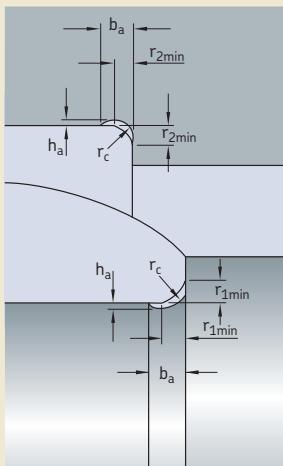

Shaft and housing fillet dimensions, no undercut

Fig. 14

Shaft and housing fillet dimensions, with an undercut**Abutment and fillet dimensions**

The abutment and fillet dimensions should be such that:

- A sufficiently large support surface is available for the bearing ring.
- Moving parts of the bearing arrangement cannot contact stationary components.
- The fillet radius should be smaller than the chamfer of the bearing.

Appropriate abutment dimensions (→ fig. 12) are provided for each bearing in the product tables. The transition from the bearing seat to the shaft or housing shoulder can be either a simple fillet (→ fig. 13) or an undercut (→ fig. 14). Dimensions for r_{amax} and r_{bmax} are listed in the product tables.

Dimensions for undercuts are provided in table 5.

The larger the fillet radius (for the simple form) of the transition to the shaft shoulder, the more favourable is the stress distribution in the shaft fillet area.

Table 5

6	8,6	0,6	6
7,5	10	0,6	7

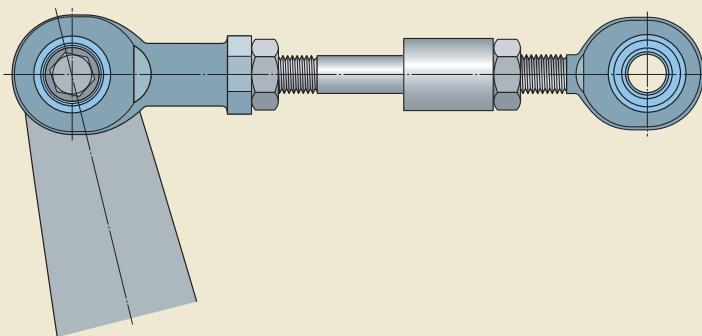

Location of rod ends

The inner rings of rod ends can be axially located by a shaft shoulder, a nut or a retaining ring.

Rod ends mounted on threaded rods or in extension tubes should be secured by an extra nut on the rod or the external thread of the rod end shank. The nut should be securely tightened against the support surface on the rod end housing or on the tube (**→ fig. 15**).

Fig. 15

Attachment of rod ends

Sealing

Most bearing arrangements must be sealed to prevent contaminants, such as dirt and moisture, from entering the bearing. The efficiency of the seal has a decisive influence on the service life of the bearing. In contrast to most other bearing types, which only move in one plane, the alignment capabilities of spherical plain bearings place additional demands on the seal.

To select appropriate seals, several factors have to be considered, including:

- the permissible angle of tilt
- the available space
- environmental conditions
- the effectiveness of the seal
- the type of lubricant and the frequency of relubrication
- the justifiable cost

Depending on the application, one or more of the above factors outweigh the others. It is therefore not possible to establish general rules for seal design.

Most SKF radial spherical plain bearing series are available with integral seals. Standard sealed bearings can increase the service life of the bearings and save space, while reducing

inventory and assembly costs. Design characteristics and suitability of the RS seals and the LS heavy-duty seals are provided in **table 6**.

Table 7 on pages 80 to 81, provides an overview of external sealing possibilities, their design characteristics and their suitability to meet different application requirements. SKF supplies most of the external seals introduced in **table 7**.

NOTE: SKF additional information about the seals referred to in **table 7 on pages 80 to 81**, refer to the *SKF Interactive Engineering Catalogue*, available online at www.skf.com.

SKF also supplies sealing strips made of felt (FS strips) or aluminium-boron silicate (FSB strips) for high temperature applications.

WARNING!

Some of the external seals listed in this table can be made of fluoro rubber. Note that fluoro rubber gives off dangerous fumes at temperatures above 300 °C and can be hazardous if touched. As handling seals made of fluoro rubber constitutes a potential safety risk, the safety precautions must always be followed. For detailed information about the safety precautions, refer to the *SKF Interactive Engineering Catalogue*, available online at www.skf.com, the *SKF General Catalogue* or the publication *Industrial shaft seals*.

Designing a bearing arrangement for easy mounting and dismounting

To facilitate mounting, the shaft ends and housing bores should have a 10 to 20 degree lead-in chamfer (**→ fig. 16**). This is particularly important for applications using larger bearings, as the rings may skew, causing damage to the mating surfaces.

To facilitate the use of withdrawal tools when removing bearings, it can be advantageous to:

- provide recesses in the shaft shoulder (**→ fig. 17**)
- provide recesses or threaded holes in the housing bore (**→ fig. 18**)

To dismount larger maintenance-free bearings with a bore diameter $d \geq 80$ mm that have a tight shaft fit, SKF recommends using the oil injection method. With the oil injection method, oil under high pressure is injected between the bearing inner ring and its shaft seat to form an oil film. This oil film separates the mating surfaces, greatly reducing the force required to dismount the bearing and virtually eliminating any risk of damage to the bearing or shaft.

To use the oil injection method, there must be an oil supply duct in the shaft as well as an oil distribution groove in the seat (**→ fig. 19**). As a general rule, the distance between the groove and the bearing side face from which mounting and dismounting are to be performed should be approximately one third of the seat width (**→ fig. 19**). Recommended dimensions for the ducts and grooves as well as for the threads for the oil supply connection are provided in **tables 8** and **9**.

Lubrication

The SKF traffic light concept

Most grease suppliers indicate the specific values for the low and high temperature limits in their product information. The SKF traffic light concept is distinctly different from that. SKF recognizes that the really important temperatures for reliable operation lie within a smaller range. This range depends largely on the type of base oil and thickener used as well as the additives. The relevant temperatures are given by the SKF traffic light concept. They are schematically illustrated in **diagrams 1 and 2** in the form of a double traffic light.

It is evident that grease in the red zones should not be applied at all, as damage may occur. Within the green zone the grease functions reliably, and the grease life can be determined accurately.

At temperatures in the amber zone above the high temperature performance limit (HTPL), grease ages and oxidize with increasing rapidity and the by-products of the oxidation have a detrimental effect on lubrication. An amber zone also exists for low temperatures. Short periods in this zone, e.g. during a cold start, are not harmful since the heat caused by friction brings the bearing temperature into the green zone.

The SKF traffic light concept – general

LTL – Low temperature limit

This limit indicates the lowest temperature at which the grease allows the bearing to be started up without difficulty.

LTPL – Low temperature performance limit

Below this limit, the supply of grease to the contact surfaces becomes insufficient.

HTPL – High temperature performance limit

Above this limit, the grease ages and oxidizes in an uncontrolled way, so that grease life cannot be determined accurately.

HTL – High temperature limit

When exceeding this limit, the grease loses its structure permanently.

The SKF traffic light concept – temperature limits for SKF greases when used in spherical plain bearings requiring maintenance

Fig. 1

Relubricating the bearing via the outer ring

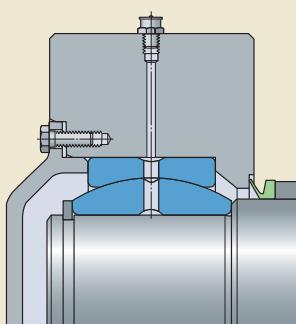

Fig. 2

Relubricating the bearing via the inner ring

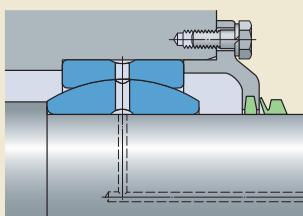

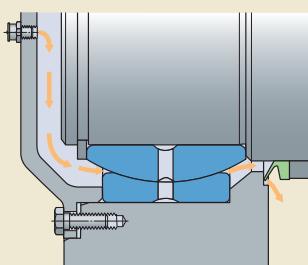

Fig. 3

Relubricating the bearing from the side

Spherical plain bearings requiring maintenance

Steel/steel radial spherical plain bearings must be relubricated to:

- reduce friction
- reduce wear
- extend bearing service life
- protect against corrosion and contaminants

The sliding contact surfaces are phosphated and treated with a “running-in” lubricant. This special surface treatment has a favourable influence during the running-in phase. The bearings must be greased prior to use and relubricated on a regular basis.

To reliably relubricate the bearings, grease ducts should be provided in the housing (→ fig. 1) or shaft (→ fig. 2) so that fresh grease can be supplied directly to the bearing. All SKF steel/steel radial spherical plain bearings (with the exception of the smallest E and ESA design bearings) have an annular groove and lubrication holes in both the inner and outer rings to facilitate lubricant distribution to the sliding surfaces of the bearing.

If the arrangement is appropriately designed, the bearing can also be supplied with grease from the side. To facilitate the passing of grease through the bearing, the grease should be prevented from exiting the bearing arrangement from the side it is supplied, e.g. by an end cover, and to provide an opening for the grease to exit on the opposite side, e.g. a V-ring seal that can open if there is pressure from the inside (→ fig. 3).

Generally, where possible, the free space surrounding the bearing should be filled with grease.

SKF recommends using SKF LGHB 2 grease to lubricate steel/steel spherical plain bearings. Its properties include:

- excellent performance under heavy loads
- very good rust inhibitor
- very good resistance to ageing
- good water resistance
- a wide operating temperature range.

If operating temperatures exceed the temperature range limits, special grease should be used (**→ table 1**).

For additional information, contact the SKF application engineering service.

¹⁾ Grease biologically degradable, for use in applications where strict ecological demands must be met and where lubrication cannot be dispensed with.

²⁾ Refer to the SKF traffic light concept, starting on **page 84**.

Maintenance-free spherical plain bearings

Steel/PTFE sintered bronze and steel/PTFE fabric sliding contact surface combinations

During operation, PTFE is transferred from the dry sliding contact surface of the outer ring to the hard chromium plated steel surface of the inner ring. Any external lubricant on the sliding contact surfaces would disturb this self-lubrication and shorten bearing service life.

As a result, these bearings must not be lubricated and do not have any relubrication facility.

Steel/PTFE FRP sliding contact surface combination

Bearings with this sliding contact surface combination are also self-lubricating and can be operated grease-free.

However, initial lubrication followed by occasional relubrication of steel/PTFE FRP bearings can extend the service life of the bearing by a factor of two or more. The inner rings of radial bearings or shaft washers of angular contact and thrust bearings are coated with a lithium base grease before leaving the factory.

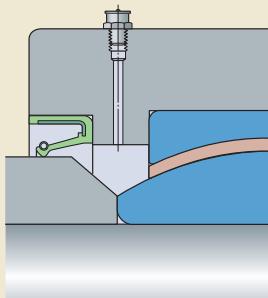

If operating conditions are such that protection against corrosion and enhanced sealing are required, the free space surrounding the bearing (\rightarrow fig. 4) can be filled with the same grease that was used to lubricate the bearing. The appropriate time to replenish or renew the grease in the bearing arrangement is determined by the operating conditions and the ageing of the grease.

Rust inhibiting, water-repellent lithium base greases with a consistency of 2 on the NGLI scale should be used. SKF recommends SKF LGEP 2 grease (\rightarrow table 1 on page 87). Greases containing molybdenum disulphide or other solid lubricants should never be used.

CAUTION: Depending on their design, SKF spherical plain bearings are either completely or partially coated with an oily preservative or filled with grease. Avoid skin contact as these substances may cause skin irritation or an allergic reaction.

Fig. 4

Relubricating the bearing from the side

Rod ends requiring maintenance

Steel/steel and steel/bronze rod ends require lubrication. To facilitate this:

- All SKF steel/steel rod ends, with the exception of small-sized E and ESA design rod ends, can be relubricated via a lubrication hole or grease fitting in the rod end housing as well as via the pin and the inner ring (→ fig. 5).
- All SKF steel/bronze rod ends can be relubricated via a lubrication hole or grease fitting in the rod end housing (→ fig. 6).

The general recommendations for steel/steel radial spherical plain bearings also apply to steel/steel rod ends as well as steel/bronze rod ends.

For steel/bronze rod ends in the SIKAC .. M and SAKAC .. M series, SKF recommends SKF LGMT 3 grease (→ table 1 on page 87). Lithium based greases with a normal consistency without solid lubricant additives can also be used.

Maintenance-free rod ends

Maintenance-free, self-lubricating rod ends are designed to be used as dry sliding bearings and must not be lubricated. Consequently, these rod ends do not have a relubrication facility in their housings.

Steel/PTFE FRP rod ends are an exception. They can be used without additional lubricant, but their service life can be extended appreciably if they are lubricated prior to use.

CAUTION: Depending on their design, SKF rod ends are either completely or partially coated with an oily preservative or filled with grease. Avoid skin contact as these substances may cause skin irritation or an allergic reaction.

Fig. 5

Relubrication facilities for steel/steel rod ends

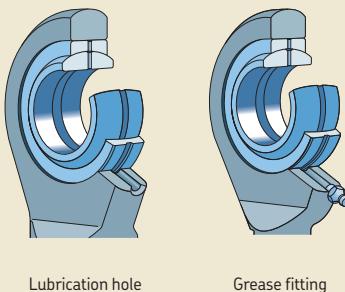

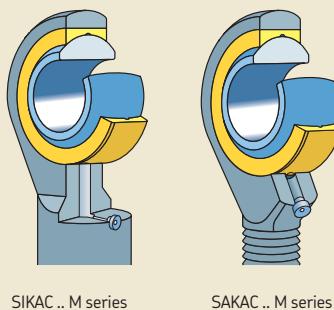

Fig. 6

Relubrication facilities for steel/bronze rod ends (sizes 6 and larger)

Relubrication

To maximize the service life of spherical plain bearings and rod ends requiring maintenance, they must be relubricated on a regular basis. This also applies to maintenance-free bearings with a steel/PTFE FRP sliding contact surface. Used grease containing wear debris and contaminants should be removed from the contact zone and replaced with fresh grease.

Determining the proper relubrication interval is extremely important because the attainable service life depends on several factors including:

- the magnitude of the load
- the type of load
- the angle of oscillation
- the frequency of oscillation
- the operating temperature
- the sealing arrangement
- other environmental conditions

Long bearing service life can be attained when the following basic relubrication rules are observed:

- the same type of grease is always used
(→ **table 1 on page 87**)
- the lubricant is applied at operating temperature
- the lubricant is applied before a long interruption, e.g. before construction or agricultural equipment is stored

Relubrication of non-locating bearings

Non-locating bearings, where axial displacement takes place along the shaft or pin, should always be relubricated via the shaft and bearing inner ring (→ **fig 2 on page 86**). By supplying lubricant in this way, grease also enters between the mating surfaces of the inner ring and shaft seat. This reduces friction and induced axial loads when axial displacement occurs.

Storage

SKF spherical plain bearings and rod ends are treated with a preservative before they are packaged. They can, therefore, be stored in their original packages for several years. However, the relative humidity in the storeroom should not exceed 60%.

NOTE: SKF also supplies a comprehensive assortment of greases for various application requirements. For additional information, refer to the catalogue *SKF Maintenance and Lubrication Products* or online at www.mapro.skf.com.

SKF has the appropriate greases for spherical plain bearings and rod ends, including the biologically degradable SKF LGGB 2 grease

Mounting

Skill and cleanliness when mounting are necessary if spherical plain bearings and rod ends are to achieve maximum service life and not fail prematurely.

Bearings and rod ends should only be removed from their packages immediately prior to mounting so that they do not become contaminated. Bearing components that could have become dirty as a result of improper handling or damaged packaging should be wiped clean with a lint-free cloth.

The sliding contact surfaces of spherical plain bearings are matched to provide favourable friction and wear characteristics. Therefore, any alteration of the sliding surfaces can reduce bearing service life. Alterations in this context also include washing or exposing the sliding surfaces to solvents, cleaners, oils or similar media.

All associated components should be clean and free of any burrs. Also make sure to check each associated component for dimensional accuracy before the installation process is started.

Spherical plain bearings

When mounting spherical plain bearings with a fractured or split outer ring, it is essential that the joint is positioned at 90° to the direction of load (→ fig. 1), otherwise service life is reduced.

Steel or plastic bands that hold together spherical plain bearing outer rings must not be removed prior to mounting. They are positioned in an annular groove and do not protrude from the outside diameter surface.

Spherical plain bearing outer rings that are axially split and bolted together must be mounted as such, without loosening the bolts.

Mechanical mounting

The following tools are suitable for mounting spherical plain bearings:

- a mounting dolly (→ fig. 2) or length of tubing; the ring with an interference fit should generally be mounted first
- a dolly having two abutment surfaces (→ fig. 3) for simultaneously mounting the bearing on the shaft and in the housing
- for larger numbers of bearings, suitable tools can be used in combination with a press (→ fig. 4)

When mounting spherical plain bearings, consider the following:

- Never use a hammer or pin punch to drive a bearing in place, as either could damage the rings (→ fig. 5).
- The mounting force should never be directed through the sliding contact surfaces (→ fig. 6). This could damage the sliding contact surfaces and/or expand fractured or split bearing outer rings, which can cause an increase in the mounting force required.

Fig. 1

Plane of fracture or split and main direction of load

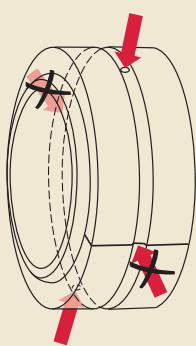

Fig. 2

Mounting with the aid of a dolly

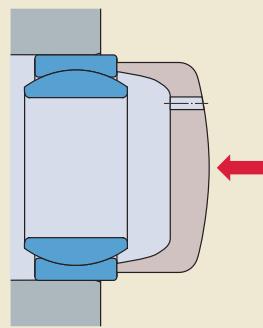

Fig. 3

Simultaneous mounting in the housing and on the shaft

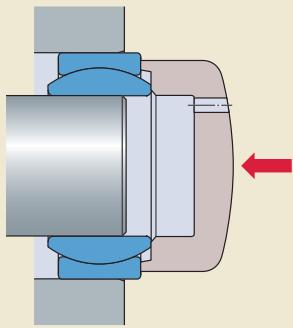

Fig. 4

Mounting using a press

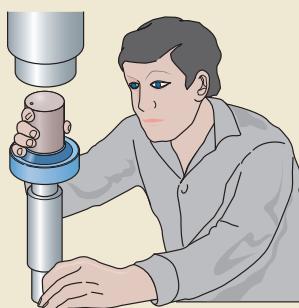

Fig. 5

Never hit the bearing rings directly

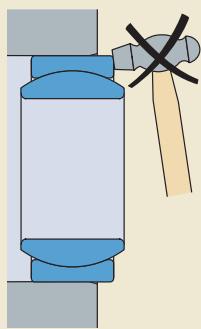

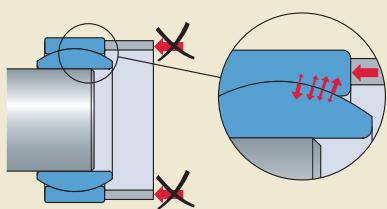

Fig. 6

Never apply the mounting force via the sliding contact surfaces

Mounting

Hot mounting

As a rule, larger bearings cannot be mounted cold because the force required to press a bearing into position increases considerably with its size. Therefore, SKF recommends the following:

- heat the bearing before it is mounted on the shaft (→ fig. 7)
- heat non-split housings before inserting the bearing

To mount a bearing on a shaft, a temperature differential of 60 to 80 °C between ambient temperature and the heated inner ring, is usually sufficient. For housings, the appropriate differential depends on the degree of interference and the seat diameter. However, a moderate

increase in temperature is usually sufficient. When heating the bearing, do not exceed the temperature limit of any associated components, such as the seals.

For an even and risk-free heat source, an induction heater should be used. The use of an SKF induction heater has a number of advantages. It heats the bearing rapidly and a built-in thermostat prevents overheating. The non-metallic components, such as the seals or PTFE fabric, remain cold as does the heater itself. SKF induction heaters automatically demagnetize the bearing after it has been heated.

Mounting bearings by cooling the shaft or the bearing is not recommended, as the very low temperatures required inevitably cause condensation, thus creating the risk of corrosion.

To ease the mounting of large bearings, particularly if they have been heated, it is possible to use slings and a hoist. Metal or textile slings placed around the outer ring can be used. A spring between the hoist hook and the sling also facilitates bearing handling (→ fig. 8).

Fig. 7

Mounting a heated bearing

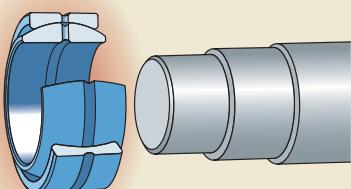

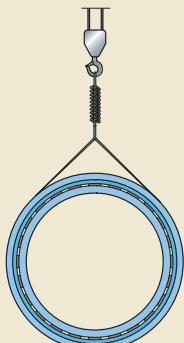

Fig. 8

Mounting a heated large bearing

WARNING!

Maintenance-free spherical plain bearings and rod ends must never be subjected to temperatures in excess of +280 °C due to the PTFE content. PTFE is completely inert below this temperature but at higher temperatures (from approx. 320 °C) it rapidly decomposes. The fluorine compounds released during this process are extremely toxic, even in small quantities, and can cause serious injury. It should also be remembered that the material is dangerous to handle once it has been overheated, even after it has cooled.

Heat-resistant gloves should be worn when handling hot components.

Rod ends

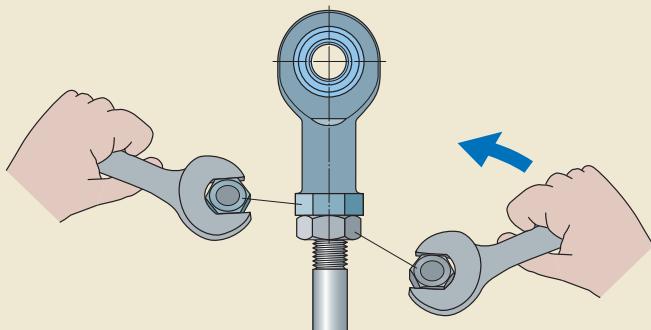

Rod ends are fitted on pins and shafts in the same way as spherical plain bearings. Slight heating reduces the force required for mounting and reduce the risk of damaging associated components.

When attaching rod ends to threaded rods or extension tubes (→ fig. 9) a counter lock nut should be used on the rod or on the external thread of the rod end. It should be securely tightened against the abutment surface on the rod end or tube.

NOTE: SKF supplies a comprehensive range of mechanical and hydraulic tools as well as heating equipment for bearing mounting and dismounting. For additional information, refer to the catalogue *SKF Maintenance and Lubrication Products* or online at www.mapro.skf.com.

Fig. 9

Securing a rod end with a right-hand thread

Dismounting

Spherical plain bearings

If bearings are to be re-used after dismounting, the same care and attention are required during dismounting as when mounting. The requisite withdrawal force should always be applied to the ring which is being dismounted.

SKF offers an assortment of different pullers to accommodate many applications. If the shaft is pre-machined to accommodate the arms of a jaw puller, then a two- or three-armed puller can be used (→ fig. 1).

In other cases where there is enough space behind the ring, a strong back puller such as the SKF TMBS series can be used (→ fig. 2).

For large bearings with an interference fit, dismounting is considerably facilitated if the SKF oil injection method is used (→ fig. 3). The oil ducts and distributor grooves should be provided when designing the bearing arrangement (→ page 82).

Small bearings can be dismounted using a mounting dolly or a length of tubing applied to the outer ring. For larger bearings with an interference fit, a mechanical or hydraulic press should be used when possible.

It is also possible to dismount a bearing from the housing bore by quickly heating the housing without heating the bearing outer ring to any extent.

Rod ends

To dismount rod ends, the lock nut securing the shank should be loosened and, if possible, the rod end should be unscrewed from its rod or tube. The rod end can then be removed from the pin or shaft in the same way as a bearing, e.g. using a puller or a press.

Fig. 1

Removing a bearing with a jaw puller

2.4 Radial spherical plain plain bearings with an extended inner ring, steel/steel, inch sizes	120

Radial spherical plain bearings requiring maintenance

A characteristic feature of SKF steel/steel radial spherical plain bearings is the outer ring, which is intentionally fractured so that it can be sprung apart to enable the inner ring to be inserted (→ fig. 1). The bearings are therefore non-separable and easy to handle.

The bearings are manganese phosphated and the sliding contact surface is then treated with a running-in lubricant. This reduces friction and wear during the running-in period. To facilitate lubrication, all bearings, with the exception of some small sizes, have an annular groove and two lubrication holes in both the inner and outer rings. Metric bearings with an outside diameter $D \geq 150$ mm also have the SKF multi-groove system (→ page 17) in the outer ring sliding contact surface as standard (→ fig. 2). Upon request, SKF can also supply smaller metric and inch size bearings with the multi-groove system.

With the multi-groove system, SKF solved the problem of lubricant starvation in steel/steel bearings. Lubricant starvation is a common cause of premature bearing failure in applications where minor alignment movements are made under heavy, constant direction loads.

The multi-groove system improves lubricant distribution in the heavily loaded zone to extend bearing service life and/or maintenance intervals.

Dimensions

The dimensions of spherical plain bearings in the GE, GEH and GEG series are in accordance with ISO 12240-1:1998.

Bearings in the GEM series, which have an extended inner ring, have a non-standard inner ring width, but otherwise have the same dimensions as GE series bearings.

Inch spherical plain bearings in the GEZ series are in accordance with the American Standard ANSI/ABMA Std. 22.2-1988.

Fig. 1

The fractured outer ring enables the bearing to be assembled

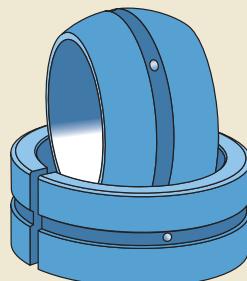

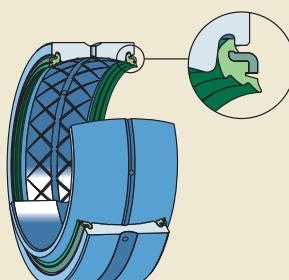

Fig. 2

Spherical plain bearing with the multi-groove system in the outer ring

Fig. 3

Spherical plain bearing with the multi-groove system, fitted with LS heavy-duty seals

Tolerances

The dimensional tolerances for metric radial spherical plain bearings requiring maintenance in the GE, GEG, GEH and GEM series are listed in **table 1**. The dimensional tolerances for inch radial spherical plain bearings in the GEZ, GEZH and GEZM series are listed in **table 2** on **page 103**. Outer ring tolerances apply to conditions before fracture and surface treatment. Accordingly, inner ring tolerances apply to rings before surface treatment.

The tolerances are in accordance with ISO 12240-1:1998 (metric bearings) and ANSI/ABMA Std. 22.2-1988 (inch bearings).

The symbols used in the tolerance tables are explained in the following:

- d nominal bore diameter
- Δ_{dmp} deviation of the mean bore diameter from the nominal
- D nominal outside diameter
- Δ_{Dmp} deviation of the mean outside diameter from the nominal
- Δ_{Bs} deviation of the single inner ring width from the nominal
- Δ_{Cs} deviation of the single outer ring width from the nominal

Radial internal clearance

Steel/steel radial spherical plain bearings are produced with Normal radial internal clearance as standard. The actual values are listed in **tables 3** and **4**. Prior to ordering, check availability of bearings with a smaller (C2) or larger (C3) radial internal clearance than Normal.

The clearance values for metric bearings are in accordance with ISO 12240-1:1998.

Materials

The inner and outer rings of SKF steel/steel radial spherical plain bearings are made of bearing steel. They are through-hardened, ground and phosphated. The sliding contact surfaces are treated with a running-in lubricant.

Depending on the bore diameter, metric bearings with a 2RS suffix have a double-lip seal made of a polyester elastomer or acrylonitrile-butadiene rubber on both sides of the bearing (→ **table 6 on page 79**). Inch bearings with a 2RS suffix have a double-lip seal made of polyurethane on both sides of the bearing.

Metric and inch bearings with the designation suffix -2LS have a sheet steel reinforced, triple-lip heavy-duty seal made of acrylonitrile-butadiene on both sides of the bearing.

Permissible operating temperature range

Open steel/steel radial spherical plain bearings have a permissible operating temperature range of -50 to +200 °C, but their load carrying capacity is reduced at temperatures above +120 °C. Bearings for higher temperature applications up to 300 °C, can be produced on request.

For sealed bearings, the permissible operating temperature range is limited by the seal material:

- -20 to +80 °C for inch RS seals
- -30 to +130 °C for metric RS seals with a bore diameter $d < 320$ mm
- -35 to +100 °C for metric RS seals with a bore diameter $d \geq 320$ mm
- -55 to +110 °C for LS seals

The operating temperature range of the grease used to lubricate the bearings must also be taken into consideration.

Table 2

Dimensional tolerances for inch bearings

Nominal diameter		GEZ, GEZH and GEZM series				Outer ring

3.1 Maintenance-free radial spherical plain bearings, steel/PTFE sintered bronze, metric sizes	132
3.2 Maintenance-free radial spherical plain bearings, steel/PTFE fabric, metric sizes	134
3.3 Maintenance-free radial spherical plain bearings, steel/PTFE fabric, inch sizes	140
3.4 Maintenance-free radial spherical plain bearings, steel/PTFE FRP, metric sizes	144

SKF manufactures maintenance-free radial spherical plain bearings in a variety of designs and a wide range of sizes. Three sliding contact surface combinations are available:

- Steel/PTFE sintered bronze, designation suffix C
- Steel/PTFE fabric, designation suffix TX
- Steel/PTFE FRP, designation suffix F

All three sliding contact surface combinations are self-lubricating. Bearings with a steel/PTFE sintered bronze or steel/PTFE fabric sliding contact surface combinations must not be lubricated. Bearings with a steel/PTFE FRP (fibre reinforced polymer) sliding contact surface combination are also maintenance-free; however, occasional relubrication is beneficial to help maximize bearing service life. To facilitate relubrication, steel/PTFE FRP bearings are equipped with lubrication facilities.

The different designs of SKF maintenance-free radial spherical plain bearings are listed in **table 3 on pages 128 to 129**. Their design depends on the size and series, with the main differences being the material or the design of the outer ring.

Dimensions

The dimensions of metric maintenance-free radial spherical plain bearings are in accordance with ISO 12240-1:1998. The dimensions of inch bearings in the GEZ series are in accordance with ANSI/ABMA Std. 22.2-1988.

Tolerances

The dimensional tolerances for metric maintenance-free radial spherical plain bearings are in accordance with ISO 12240-1:1998 and listed in **table 1**.

The dimensional tolerances for inch bearings in the GEZ series are in accordance with ANSI/ABMA Std. 22.2-1988 and listed in **table 2**. The symbols used are explained in the following:

d	nominal bore diameter
Δ_{dmp}	deviation of the mean bore diameter from the nominal
D	nominal outside diameter
Δ_{Dmp}	deviation of the mean outside diameter from the nominal
Δ_{Bs}	deviation of the single inner ring width from the nominal
Δ_{Cs}	deviation of the single outer ring width from the nominal

For the TX and TXG3 designs, outer ring tolerances apply to dimensions before fracture.

Table 3

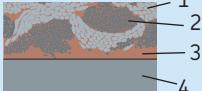

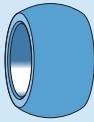

Design of maintenance-free radial spherical plain bearings

Sliding contact surface combination	Steel/PTFE sintered bronze	Steel/PTFE fabric	Steel/PTFE FRP
Seals	Available on request	Bearings with designation suffix -2RS or -2LS (depending on bearing size) have a double- or triple-lip seal on both sides (→ page 79)	None
RS design			
LS design			
Permissible operating temperature range	-50 to +150 °C, for short periods up to +280 °C	Bearings without seals: -50 to +150 °C Bearings with RS seals: with a bore diameter $d < 320 \text{ mm}$: -30 to +130 °C with a bore diameter $d \geq 320 \text{ mm}$: -35 to +100 °C Bearings with LS seals: -50 to +110 °C	-40 to +75 °C, for short periods up to +110 °C
			
	Reduced carrying capacity above 80 °C	Reduced carrying capacity above 65 °C for both sealed and unsealed bearings	Reduced carrying capacity above 50 °C
Lubrication (refer to the section <i>Lubrication</i> , starting on page 84)	Self-lubricating; the bearings must not be lubricated	Self-lubricating; the bearings must not be lubricated	Greased before leaving factory, self-lubricating capability, however occasional relubrication extends service life

Radial internal clearance, preload

Maintenance-free radial spherical plain bearings with a bore diameter $d \leq 90$ mm either have an internal clearance or a slight preload (negative clearance) depending on their design. Therefore, these bearings can only be provided with an upper limit for bearing internal clearance. The lower limit must be assessed by the frictional moment, resulting from the preload (negative clearance).

The radial internal clearance and the upper limit of the permissible frictional moment of bearings with a steel/PTFE sintered bronze sliding contact surface are listed in **table 4**. The values for the clearance limits of bearings with a steel/PTFE fabric and a steel/PTFE FRP sliding contact surface combination are listed in **tables 5 to 8**.

Materials

The materials for the inner ring, outer ring, sliding layer and seals, where applicable, are listed in **table 3** on **pages 128 to 129**.

Permissible operating temperature range

The permissible operating temperature range of maintenance-free radial spherical plain bearings depends on the sliding contact surface combination and the material of the seals (→ **table 3** on **pages 128 to 129**). However, if the load carrying capacity of the bearings is to be fully exploited, the temperature range must be narrowed. Depending on the application, it is possible to operate at temperatures above the upper limit for brief periods. For additional information, contact the SKF application engineering service.

4.1 Maintenance-free angular contact spherical plain bearings, steel/PTFE FRP	156

Angular contact spherical plain bearings

As their name implies, the sliding contact surfaces of angular contact spherical plain bearings are spherical in shape and inclined at an angle to the bearing axis (→ **fig. 1**). Consequently, these bearings are well suited for accommodating combined (radial and axial) loads. Single angular contact spherical plain bearings can only accommodate axial loads acting in one direction. These bearings can be separated, enabling the rings to be mounted separately.

SKF manufactures steel/PTFE FRP (fibre reinforced polymer containing PTFE) maintenance-free angular contact spherical plain bearings as standard. Designs with other sliding surface combinations are available on request (→ *Special designs*, starting on **page 154**).

Dimensions

The boundary dimensions of SKF angular contact spherical plain bearings are in accordance with ISO 12240-2:1998.

Tolerances

The dimensional tolerances for SKF angular contact spherical plain bearings are listed in **table 1** and are in accordance with ISO 12240-2:1998.

The symbols used in the tolerance table are explained in the following:

d	nominal bore diameter
Δ_{dmp}	deviation of the mean bore diameter from the nominal
D	nominal outside diameter
Δ_{Dmp}	deviation of the mean outside diameter from the nominal
Δ_{Bs}	deviation of the single inner ring width from the nominal
Δ_{Cs}	deviation of the single outer ring width from the nominal
Δ_{Ts}	deviation of the single bearing width from the nominal

Table 1

Dimensional tolerances for angular contact spherical plain bearings

Nominal diameter d, D over incl.		Inner ring Δ_{dmp} high low		Δ_{Bs} high low		Outer ring Δ_{Dmp} high low		Δ_{Cs} high low		Bearing width $\Delta_{Ts}^{1)}$ high low	
		μm		μm		μm		μm		μm	
18	50	0	-12	0	-240	0	-14	0	-240	+250	-400
50	80	0	-15	0	-300	0	-16	0	-300	+250	-500
80	120	0	-20	0	-400	0	-18	0	-400	+250	-600
120	150	-	-	-	-	0	-20	0	-500	-	-
150	180	-	-	-	-	0	-25	0	-500	-	-

¹⁾ The tolerance of the bearing width depends on d.

Radial internal clearance, preload

The internal clearance of a single angular contact spherical plain bearing is only obtained after mounting and depends on the adjustment against a second bearing that provides axial location in the opposite direction. Angular contact spherical plain bearings are generally mounted as pairs in a back-to-back (\rightarrow fig. 2) or face-to-face arrangement (\rightarrow fig. 3). The bearings are adjusted against each other by axially displacing one bearing ring until a specific bearing load of 10 N/mm^2 is obtained. The preload prevents some of the deformations that typically occur under load and after a brief running-in period. When adjusting a new bearing arrangement for the first time, the specific bearing load of 10 N/mm^2 is achieved when the frictional moment and the axial preload force are in the ranges listed in table 2.

GAC 120 F	317	69 500

Materials

The inner and outer rings of SKF angular contact spherical plain bearings are made of bearing steel that has been through-hardened and ground. The sliding layer of fibre reinforced polymer, containing PTFE, is injection moulded onto the outer ring (→ fig. 4). The sliding surface of the inner ring is hard chromium plated and coated with a lithium base grease.

Permissible operating temperature range

Spherical plain bearings with a steel/PTFE FRP sliding contact surface combination can be used for operating temperatures ranging from -40 to $+75$ °C. For brief periods, temperatures up to 110 °C can be tolerated. However, keep in mind that the load carrying capacity of the bearing is reduced at temperatures that exceed 50 °C. For additional information, contact the SKF application engineering service.

Special designs

Special operating conditions may require angular contact spherical plain bearings with a steel/PTFE fabric or steel/steel sliding contact surface combination. These bearings are available on request.

Bearings with a maintenance-free steel/PTFE fabric sliding contact surface combination (→ fig. 5) should be used when lubricant-free operation is specified. These bearings can accommodate heavy loads, preferably in a constant direction.

Steel/steel bearings (→ fig. 6) are typically used in applications where operating temperatures or load frequencies are high, or where heavy or shock loads occur. To operate properly, steel/steel bearings must be provided with an adequate supply of lubricant. Depending on the operating conditions, the sliding surface of the outer ring may be equipped with various multi-groove patterns (→ figs. 7 and 8). For additional information, contact the SKF application engineering service.

Upon request, inch steel/steel angular contact spherical plain bearings are also available as double direction angular contact spherical plain bearings. Double direction bearings can be used instead of two angular contact bearings in a face-to-face arrangement, or as a high capacity

radial bearing. Double direction angular contact spherical plain bearings consist of two outer rings and a standard inner ring. SKF supplies these bearings with (GEZPR .. S series) or without (GEZP .. S series) a shim between the two outer rings. The shim simplifies installation and optimizes axial internal clearance within the bearing (→ fig. 9).

Special designs	162
Product tables	164
5.1 Maintenance-free thrust spherical plain bearings, steel/PTFE FRP	164

Thrust spherical plain bearings

Thrust spherical plain bearings have a convex spherical surface on the shaft washer and a corresponding concave spherical surface in the housing washer (→ fig. 1). They are intended to accommodate primarily axial loads but can also accommodate combined (radial and axial) loads. The radial load component of a combined load should not exceed 50% of the axial load component. When radial loads are larger, it is advisable to combine thrust bearings with radial bearings in the GE dimension series (→ fig. 2). Thrust spherical plain bearings are separable, e.g. shaft and housing washers can be mounted separately.

SKF manufactures thrust spherical plain bearings with the maintenance-free steel/PTFE FRP (fibre reinforced polymer containing PTFE) sliding contact surface combination as standard. Other sliding surface combinations are available on request (→ *Special designs*, page 162).

Dimensions

The principal dimensions of SKF thrust spherical plain bearings are in accordance with ISO 12240-3:1998.

Tolerances

The dimensional tolerances for SKF thrust spherical plain bearings are listed in **table 1** and are in accordance with ISO 12240-3:1998.

The symbols used in the tolerance table are explained in the following:

d	nominal bore diameter (shaft washer)
Δ_{dmp}	deviation of the mean bore diameter from the nominal
D	nominal outside diameter (housing washer)
Δ_{Dmp}	deviation of the mean outside diameter from the nominal
Δ_{Bs}	deviation of the single shaft washer height from the nominal
Δ_{Cs}	deviation of the single housing washer height from the nominal
Δ_{Ts}	deviation of the single thrust bearing height from the nominal

Fig. 1

Standard thrust spherical plain bearing, steel/PTFE FRP

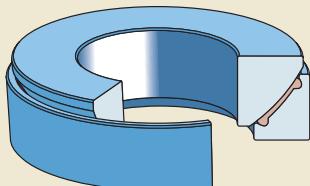

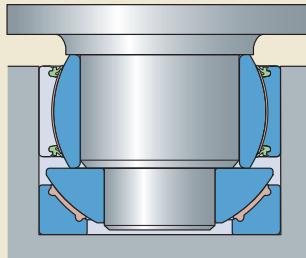

Fig. 2

Combination of a radial and a thrust spherical plain bearing

Materials

Shaft and housing washers for SKF thrust spherical plain bearings are made of bearing steel that has been through-hardened and ground. The sliding surface of the shaft washer is hard chromium plated and coated with a lithium base grease. The sliding layer of fibre reinforced polymer, containing PTFE, is injection moulded onto the housing washer.

Permissible operating temperature range

Thrust spherical plain bearings with a steel/PTFE FRP sliding contact surface combination can be used for operating temperatures ranging from -40 to $+75$ °C. For brief periods, temperatures up to 110 °C can be tolerated. However, keep in mind that the load carrying capacity of the bearing is reduced at temperatures that exceed 50 °C. For additional information, contact the SKF application engineering service.

¹⁾ The tolerance of the bearing height is dependent on d.

Special designs

Special operating conditions may require thrust spherical plain bearings with a steel/steel or steel/PTFE fabric sliding contact combination, which are available on request.

Steel/steel bearings (→ fig. 3) are typically used in applications where operating temperatures or load frequencies are high, or where heavy loads or shock loads occur. Steel/steel bearings must be provided with an adequate supply of lubricant. Depending on the operating conditions, the sliding surface of the outer ring may be equipped with various multi-groove patterns.

Bearings with a maintenance-free steel/PTFE fabric sliding contact surface (→ fig. 4) should be used when lubricant-free operation is specified. These bearings can accommodate heavy loads, preferably in a constant direction.

Rod ends requiring maintenance

SKF manufactures rod ends requiring maintenance with a steel/steel or a steel/bronze sliding contact surface combination.

Steel/steel rod ends consist of a rod end housing and a steel/steel radial spherical plain bearing from the standard assortment, where the outer ring is secured in the housing. These rod ends are available with a female thread (→ fig. 1), male thread (→ fig. 2) or a welding shank (→ fig. 3).

Steel/bronze rod ends consist of a rod end housing and a steel/bronze spherical plain bearing. These bearings have an inner ring made of steel and an outer ring made of bronze. The bearing is held in position by staking the housing on both sides of the outer ring. These rod ends are available with a male or female thread.

SKF supplies rod ends with a threaded shank with a right-hand thread as standard. With the exception of rod ends with the designation suffix VZ019, all rod ends are also available with a left-hand thread. They are identified by the designation prefix L.

Dimensions

The dimensions of SKF rod ends requiring maintenance are in accordance with the standards listed in **table 1**.

Male and female threads of SKF rod ends are in accordance with ISO 965-1:1998, except for rod ends with female thread having the designation suffix /VZ019, which is in accordance with ISO 8139:2009.

Tolerances

SKF rod end inner ring dimensional tolerances are in accordance with ISO 12240-4:1998. The tolerances for the steel/steel rod end inner rings are listed in **table 3** and the tolerances for steel/bronze rod end inner rings are listed in **table 2**.

The symbols used in these tables are explained in the following:

d nominal bore diameter

Δ_{dmp} deviation of the mean bore diameter from the nominal

Δ_{Bs} deviation of the single inner ring width from the nominal

Rod ends requiring maintenance

Permissible operating temperature range

The permissible operating temperature range for SKF rod ends requiring maintenance depends on the rod end housing, the bearing, the bearing seals and the grease used for lubrication. The values for the permissible operating temperature range are listed in **table 7**.

The load carrying capacity of the rod end is reduced at temperatures above 100 °C. For temperatures below 0 °C, check to be sure that the fracture toughness of the rod end housing is adequate for the intended application.

Maintenance-free rod ends

SKF manufactures maintenance-free rod ends with three different sliding contact surface combinations in different series:

- Steel/PTFE sintered bronze (**→ fig. 1**):
 - SI(L) .. C series
 - SA(L) .. C series
- Steel/PTFE fabric (**→ fig. 2**):
 - SI(L) .. TXE-2LS series
 - SI(L)A .. TXE-2LS series
 - SA(L) .. TXE-2LS series
 - SA(L)A .. TXE-2LS series
- Steel/PTFE FRP (**→ fig. 3**):
 - SI(L)KB .. F series
 - SA(L)KB .. F series

Rod ends with either a steel/PTFE sintered bronze or steel/PTFE fabric sliding contact surface combination contain a bearing from the standard assortment. The outer ring is staked in place in the housing.

Rod ends with a steel/PTFE FRP sliding contact surface combination consist of a rod end housing and a spherical plain bearing inner ring. Between the housing and the inner ring, a sliding layer of fibre reinforced polymer, containing PTFE, is moulded to the housing.

SKF supplies maintenance-free rod ends with a threaded shank with a right-hand thread as standard. With the exception of rod ends with the designation suffix VZ019, all rod ends are also available with a left-hand thread. They are identified by the designation prefix L.

Dimensions

The dimensions of SKF maintenance-free rod ends are in accordance with ISO 12240-4:1998.

Male and female threads of SKF rod ends are in accordance with ISO 965-1:1998, except for rod ends with female thread having the designation suffix /VZ019, which is in accordance with ISO 8139:2009.

Materials

SKF rod end housings for maintenance-free bearings are made of materials as listed in **table 3**.

Details of the materials used for the maintenance-free radial spherical plain bearings incorporated in the rod ends are listed in **table 3** on **pages 128 to 129**.

The inner ring of rod ends with a steel/PTFE FRP sliding contact surface combination is made of bearing steel. The ring is through-hardened and ground. The sliding contact surface of the inner ring is hard chromium plated. The sliding layer consists of a fibre reinforced polymer, containing PTFE.

Permissible operating temperature range

The permissible operating temperature range for SKF maintenance-free rod ends depends on the rod end housing, the incorporated bearing and the bearing seals. The values for the permissible operating temperature range are listed in **table 4**.

The load carrying capacity of the rod end is reduced at temperatures above 100 °C. For temperatures below 0 °C, check to be sure that the fracture toughness of the rod end housing is adequate for the intended application.

Fatigue strength

In all applications where a rod end is subjected to alternating loads, loads that vary in magnitude or where failure of a rod end is dangerous, make sure that the selected rod end has sufficient fatigue strength.

Table 3

Housing materials for maintenance-free rod ends

Series	Size	Material	Material No.
SA(A) SI(A)	6 to 80	Heat treatable steel C45V, zinc coated and chromatized	1.0503
SAKB SIKB	5 to 12	Free-machining steel, 1.0718 zinc coated and chromatized	
	14 to 22	Heat treatable steel C35N, zinc coated and chromatized	1.0501

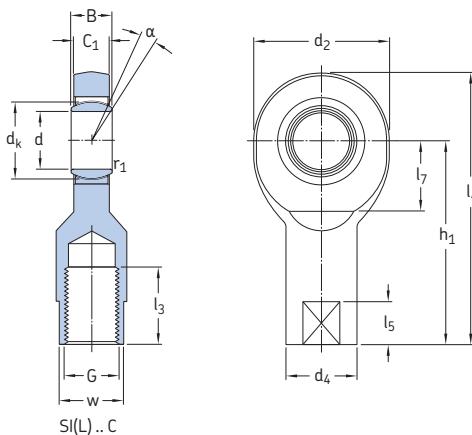

Table 4

Permissible operating temperature range for maintenance-free rod ends

Rod end sliding contact surface combination	Permissible operating temperature range ¹⁾		Reduced load carrying capacity
	from	incl.	
–	–	–	–
Steel/PTFE sintered bronze	-50	+150	+80
Steel/PTFE fabric	-40	+110	+65
Steel/PTFE FRP	-40	+75	+50

¹⁾ For temperatures below 0 °C, make sure that the fracture toughness of the rod end housing is adequate for the intended application.

Other SKF plain bearings and special solutions

Spherical plain bearings for road vehicles.....	208
Plain bearings for railway vehicles	208
Bushing units for off highway vehicles	208
Spherical plain bearings and rod ends for the aircraft industry.....	209
Bushings, thrust washers and strips.....	209
Rod ends for the food industry	210

Spherical plain bearings for road vehicles

SKF spherical plain bearings or bearing units are also available for special applications. Therefore, SKF works closely with the customer to develop customized products, e.g. solutions for centring propeller shafts or gear shifts.

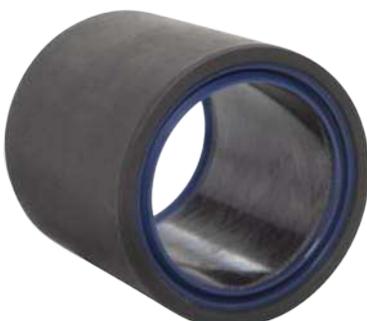

Plain bearings for railway vehicles

The SKF assortment of plain bearings for railway vehicles includes bogie swivel bearings for trams and heavy-duty goods wagons as well as spherical plain bearings and rod ends for transverse stabilizers, tilting mechanisms etc.

Bushing units for off-highway vehicles

Many off-highway vehicles have bushings made of steel or bronze that require relubrication. SKF has developed state-of-the-art bushing units with seals. As these units do not require grease, costs are reduced and productivity is increased.

Spherical plain bearings and rod ends for the aircraft industry

SKF supplies a wide assortment of special spherical plain bearings and rod ends in various designs and materials for aerospace applications worldwide. The main applications are airframe bearings for the transmission of rotating, tilting and oscillating movements as used in undercarriages, spoilers, height and side rudders, wing flaps etc.

Bushings, thrust washers and strips

SKF offers a wide assortment of bushings available from stock. Bushings are suitable for rotating, oscillating and linear movements and are available as cylindrical or flanged designs.

Thrust washers are intended for applications where axial space is limited, maintenance is not possible and where lubricant starvation can occur.

SKF also supplies strips made of the same materials as thrust washers. They can be bent, pressed or coined to form flat linear guides, e.g. L-shaped or V-shaped profiles, or other types of dry sliding components.

Different materials meet different requirements:

- solid bronze, the traditional robust material
- sintered bronze with oil impregnation, for high sliding velocities
- wrapped bronze with lubrication pockets, for contaminated environments
- PTFE composite with reduced friction, for long service life
- POM composite, for minimal maintenance under arduous conditions
- PTFE polyamide, cost-effective and maintenance-free
- filament wound, for extreme conditions

Rod ends for the food industry

The food and beverage processing industries have unique requirements. Depending on the application, equipment has to withstand the following influences:

- hot, cold or wet environments
- frequent wash downs
- exposure to harsh cleaning agents
- food and liquid contaminants
- a variety of chemicals

To deal with these challenging operating conditions, SKF offers rod ends with a stainless steel housing or with a composite housing. Both series are equipped with a stainless steel inner ring and an injection moulded PTFE FRP dry sliding layer. The used materials provide the following properties:

- corrosion resistant
- good wear resistance
- low friction
- cost-effective
